they bind with positive cooperativity, and this interaction is crucial to repressor action<sup>4</sup>. We define the intrinsic affinity of each site for a repressor dimer as that observed in in vitro binding assays using DNA with a single functional site. Such experiments show that the independent affinities of  $O_R2$  and  $O_R3$  are about equal, and  $\sim 15$ -fold less than that of  $O_R1$ . However, when DNA containing all three operators, arranged as on the wild-type genome, is used, repressor binds to  $O_R1$  and  $O_R2$  cooperatively, but  $O_R3$  only binds repressor at much higher concentrations. The explanation for this lies in the interaction of repressors bound at  $O_R1$  and  $O_R2$ : repressor bound to  $O_R1$  raises the repressor-binding affinity of site  $O_R2$ , but not that of  $O_R3$ . The concentration of repressor in a lysogen is such that  $O_R1$  and  $O_R2$  are virtually saturated, but  $O_R3$  is largely unbound<sup>5,6</sup>.

Interaction between repressor dimers bound to sites  $O_R2$  and  $O_R3$  can be studied when  $O_R1$  is non-functional because of mutation. Repressor cannot then bind to  $O_R1$ , and a repressor bound to  $O_R2$  is free to interact with another at  $O_R3$ . As a result, the affinity of repressor for site  $O_R3$  is raised and that for  $O_R2$  is lowered relative to the wild type. Thus, a repressor dimer bound to  $O_R2$  interacts predominantly with another at  $O_R1$  (on a wild-type template) or with another at  $O_R3$  (on a mutant template in which  $O_R1$  has been destroyed). (We have called this phenomenon 'alternate pairwise cooperativity', and will return to its possible physiological significance later.) The  $O_R1-O_R2$  interaction predominates on a wild-type operator because  $O_R1$  is the tightest binding site.

We believe that these cooperative interactions are mediated by contacts between the carboxy-terminal domains or the domain connector regions of adjacently bound repressor dimers, because isolated amino-terminal domains bind to the three  $O_R$  sites specifically but non-cooperatively<sup>4</sup>. This result argues that the cooperativity is not due to a change in DNA structure induced by repressor binding. In addition, repressor at high concentrations in solution forms tetramers and higher oligomers<sup>8,10,14</sup>, perhaps using the same contacts as those involved in the cooperative binding to adjacent operator sites. We have suggested<sup>1,4</sup> that the inability of a repressor dimer bound to  $O_R 2$  to interact simultaneously with others at both  $O_R 1$  and  $O_R 3$  may be due to the limited flexibility and/or size of the connectors.

**Activation of P\_{\rm RM}.** We believe that repressor stimulates transcription from  $P_{\rm RM}$  by providing a favourable protein-protein contact with RNA polymerase <sup>1,6,7</sup>. The evidence for this view includes the following observations: (1) a repressor dimer bound to  $O_{\rm R}2$  stimulates transcription of  $P_{\rm RM} \sim 10$ -fold both in vivo and in vitro <sup>2,6,7</sup>. The primary role of  $O_{\rm R}1$  in this regard is to ensure that a repressor is bound to  $O_{\rm R}2$ . (2) Repressor and RNA polymerase bind to DNA cooperatively. For example, using DNase I as a probe, we found that formation of active ('open') complexes of RNA polymerase with  $P_{\rm RM}$  is enhanced if repressor is first bound to  $O_{\rm R}1$  and  $O_{\rm R}2$ . Conversely, when polymerase

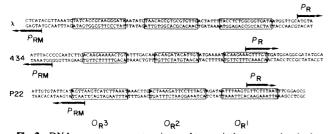

Fig. 2 DNA sequences, operator sites and transcription start-points in the right operators of  $\lambda$ , 434 and P22.  $O_R 1$ ,  $O_R 2$  and  $O_R 3$  are the sites recognized by the phage repressors. In the case of  $\lambda$ , we know that the three sites are also recognized by cro, and we presume that this is the case for 434 and P22 as well. Arrows mark the transcription start-points for the promotors  $P_R$  and  $P_{RM}$ . The operator-promoter regions are oriented so that in each case the repressor gene is transcribed to the left and the cro gene to the right. The  $\lambda$  operator sites consist of 17 bp; adjacent sites in  $O_R$  are separated by 6 and 7 bp. The 434 and P22 operator sites are 14 and 18 bp long, respectively. The 434 spacers consist of 8 and 9 bp, those of P22, 5 and 7 bp. Each operator site exhibits partial twofold rotational symmetry.

was bound to  $P_{\rm RM}$  (in the absence of repressor), the subsequent binding of repressor to  $O_{\rm R}2$  was similarly enhanced (A.J. and M.P., unpublished results). (In this experiment,  $O_{\rm R}1$ ,  $P_{\rm R}$  and  $O_{\rm R}3$  were made nonfunctional by mutation.) D. K. Hawley and W. R. McClure (personal communication) have reached similar conclusions and have further found that repressor stimulates formation of 'open' (but not 'closed') complexes of RNA polymerase with  $P_{\rm RM}$  (see refs 15–17). (3) Repressor bound at  $O_{\rm R}2$  is very close to (and may contact) polymerase at  $P_{\rm RM}$ . Figure 3b, which shows phosphates in close contact with repressor at  $O_{\rm R}2$  (and at  $O_{\rm R}1$ ) and polymerase at  $P_{\rm RM}$ , suggests that the proteins closely approach the same phosphate (and presumably, each other) between bases at positions -36 and -37 from the startpoint of  $P_{\rm RM}$  transcription (see Fig. 3 legend).

We believe that, as indicated in Fig. 3a, it is the aminoterminal domain of repressor that contacts RNA polymerase at  $P_{RM}$  and thus stimulates transcription from this promoter. Four lines of evidence suggest this. First, the purified amino-terminal domain of repressor activates transcription of  $P_{RM}$  in vitro 12 Second, RNA polymerase bound at  $P_{RM}$  enhances the binding of this amino-terminal domain to  $O_R2$  (A.J. and M.P., unpublished results). Third, a repressor fragment comprising the aminoterminal domain of repressor, when produced in large amounts, activates  $P_{RM}$  in vivo<sup>12</sup>. Fourth, a mutant of repressor has been isolated that represses  $P_{\rm R}$  but fails to stimulate  $P_{\rm RM}$  (as measured in vivo or in vitro<sup>69</sup>). The mutant repressor binds to  $O_R1$  and  $O_R2$  cooperatively with an affinity indistinguishable from that of wild-type. Plausibly this mutant maintains the structure(s) required for tight cooperative binding to DNA but lacks those necessary to interact with RNA polymerase. The mutation causes the change gly-arg at position 43 in the amino-terminal domain of repressor69

None of the experiments described above definitively excludes the possibility that repressor bound to  $O_R2$  stimulates  $P_{RM}$  by changing DNA structure. However, as repressor has little effect on the pitch of the DNA helix<sup>18</sup>, we find no reason to invoke an explanation involving changed DNA structure.

#### Induction and the role of cro

When Escherichia coli is treated with any of a variety of mutagens/carcinogens (as defined by the Ames test<sup>19</sup>), a set of genes known collectively as the 'SOS functions' is turned on (for reviews see refs 20, 21). One such gene encodes the recA protein which, when present in the low levels found in uninduced cells, catalyses genetic recombination. The recA protein is also a protease and, after an inducing treatment, it is produced at elevated levels and efficiently cleaves the  $\lambda$  repressor monomer at a specific site between the two domains<sup>22,23</sup>. (In vitro, this reaction requires cofactors presumably similar to those produced in vivo in response to inducing treatments.) The free amino-terminal repressor fragments produced by the cleavage cannot dimerize efficiently, and therefore cannot bind tightly to the operator<sup>11,12</sup>. The over-production and activation of recA (both probably required for extensive repressor cleavage) are transient phenomena, lasting for ~1 h after a typical inducing treatment (see refs 20, 24).

As the repressor in a lysogen is inactivated by cleavage,  $P_R$  is the first  $\lambda$  lytic promoter to be derepressed. This occurs because repressor binds less tightly to the sites in  $O_R$  than to those in  $O_L$ , the other major  $\lambda$  operator  $^{25,26}$ . The first new phage protein made is the product of the cro gene. The cro protein is a dimer (monomer length 66 amino acids)  $^{27,28}$  which, like the  $\lambda$  repressor, recognizes the three operator sites in  $O_R$ . DNA-bound cro is centred at each site identically to repressor, covering the same face of the helix and apparently contacting many of the same functional groups  $^{26}$ . Unlike the  $\lambda$  repressor, however, cro binds to the three  $O_R$  sites non-cooperatively, and its order of affinity to the three sites is reversed  $^{3,4}$ . That is, cro binds most tightly to  $O_R 3$ , and only at higher concentrations does it occupy  $O_R 2$  and  $O_R 1$ . Hence, after destruction of the repressor, cro is synthesized and first occupies  $O_R 3$ , as shown in Fig. 3e. In this configuration,  $P_{RM}$  is repressed and  $P_R$  is accessible to RNA

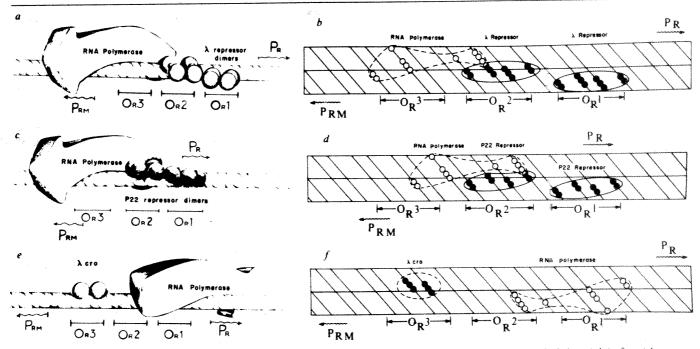

Fig. 3 Configuration of molecules bound to  $O_R/P_R$  in a  $\lambda$  lysogen (a, b), in a P22 lysogen (c, d), and during the early stages of  $\lambda$  lytic growth (e, f). a,  $\lambda$  lysogen: showing the topography of  $\lambda$  repressor dimers bound at  $O_R1$  and  $O_R2$ . This arrangement results in repression of  $P_R$  and activation of  $P_{RM}$ . b, Projection diagram showing the topography of  $\lambda$  repressor dimers bound at  $O_R1$  and  $O_R2$  and RNA polymerase bound to  $P_{RM}$ . The  $\lambda$   $O_R$  region of a is shown as a cylindrical projection (adopted from ref. 65) of B-form DNA with 10.4 bp per turn  $^{66}$ . ♠ Phosphates in close contact with bound  $\lambda$  repressor (see below). ⊖, phosphates believed to be in close contact with RNA polymerase bound at  $P_{RM}$  (see below). The solid and broken contour lines were drawn merely to group the phosphate contacts, not to imply the shapes of the DNA interaction sites. Note that the phosphate closely approached by both polymerase and repressor is marked by ⊕ c, P22 lysogen; dimers of P22 repressors are bound cooperatively to  $O_R1$  and  $O_R2$ , repressing  $P_R$  and activating  $P_{RM}$ . d, Topography of P22 repressors bound to  $O_R1$  and to  $O_R2$  and RNA polymerase bound to  $P_R$ . The symbols are as in b. Note that the relative positioning of P22 repressor at  $O_R2$  and polymerase at  $P_{RM}$  differs from that in the case of  $\lambda$  (b). e,  $\lambda$  lytic growth: after induction of a  $\lambda$  lysogen, cro proteins binds to  $O_R3$  thereby repressing  $P_RM$  and permitting  $P_R$  transcription. The precise positioning of these regulatory molecules on the DNA helix is based on the results of chemical probe experiments, some of which are summarized in e, e and e. Topography of  $\lambda$  cro bound to e0, and RNA polymerase bound to e1. Symbols are as above, cro makes four fewer phosphate contacts at each operator site than does repressor. The phosphates in close contact with a bound  $\lambda$  repressor e6.  $\mu$ 6 cro  $\mu$ 8 and P22 repressor  $\mu$ 9 were determined using the method of Maxam and Gilbert (pe

polymerase<sup>3,6</sup>. (When bound to  $O_R3$ , cro has no effect on  $P_R$  which, unlike  $P_{RM}$ , requires no auxiliary factor to function maximally.) Soon after lytic growth has commenced, as the concentration of cro increases, it turns down transcription from  $P_R$  by binding to  $O_R1$  and  $O_R2$ . This repression of early functions (including the production of cro) is essential for lytic growth<sup>29</sup>.

Two additional experiments (A.J., R. Maurer and M.P., unpublished results) emphasize the importance of the  $cro-O_R3$  interaction for induction. In the first, we studied  $\lambda$  lysogens bearing a plasmid which directs synthesis of cro under the control of the *lac* promoter. Synthesis of cro from the plasmid causes the lysogen to induce, even in the absence of repressor inactivation. This effect requires that the prophage carries an intact  $O_R3$ . We imagine that in this experiment, cro binds to  $O_R3$  and shuts off  $P_{RM}$ , and thus the production of repressor. Then, as the cells divide, repressor is diluted and induction occurs. The second experiment shows that binding of cro to  $O_R3$  is critical for efficient induction. We found that prophages mutated at  $O_R3$  in such a way that cro binds poorly, induce much less efficiently in response to UV irradiation than do wild-type prophages.

Once a phage genome reaches the state shown in Fig. 3e, we believe that it is committed to grow lytically. Hence, we view the two configurations of Fig. 3a and e as alternative states of the phage. Following induction, a prophage can be 'frozen' in the otherwise transient lytic state shown in Fig. 3e if it carries mutations which prevent expression of lytic genes other than  $cro^{30}$ . When the lysogenic bacterium bearing the mutant prophage is induced, it switches from the normal state where repressor but not cro is synthesized, to a new state in which cro but not repressor is synthesized (Fig. 3e). This new state, called 'anti-immune', like the normal lysogenic state, is inherited by subsequent generations.

#### Related phages

Which of the attributes of  $\lambda$  described above are vital to its life-cycle, and which are peculiar, perhaps accidental, to the  $\lambda$  case? To explore these questions, we now compare  $\lambda$  with two other phages, 434 and P22, to see which features are held in common. These other phages share with  $\lambda$  many basic biological properties; in particular, they all form UV-inducible lysogens. The genomes of the coliphages 434 and  $\lambda$  and of the Salmonella phage P22 are similarly organized, and share regions of homology<sup>31,32</sup>. Despite these similarities, the nucleotide sequences of the operators (Fig. 2) and the amino acid sequences of the repressors and cro proteins differ substantially. In particular, the repressor and cro of one phage do not recognize the operators of the others.

Nevertheless, we now argue that despite differences in operators, promoters and regulatory proteins, the following description holds for all three phages. The right-hand operator contains three repressor binding sites, two of which,  $O_R 1$  and  $O_R 2$ , are filled by repressor in a lysogen. This state depends on cooperative interactions between adjacent repressor dimers. Repressor monomers have two structural domains and are in equilibrium with dimers, the DNA-binding form. Repressor dimers occupying sites  $O_R 1$  and  $O_R 2$  turn off transcription from  $P_R$  and turn on that from  $P_{RM}$ . On UV induction, the repressor is cleaved and thereby inactivated, and the first protein synthesized from  $P_R$  is cro. The cro protein binds first to  $O_R 3$  to turn off repressor synthesis and later binds to  $O_R 1$  and  $O_R 2$  to decrease early lytic transcription.

The pictures we have developed for 434 and P22 are based on extensive experiments, in vivo and in vitro, similar to those performed for the analysis of  $\lambda$  (see ref. 1). In each case, plasmids that direct synthesis of large and variable amounts of the regulatory proteins were constructed by recombination in

vitro. The effects of repressor in vivo were analysed using these plasmids and other DNA molecules in which transcription of the lacZ gene was directed by a phage  $P_{\rm RM}$  or  $P_{\rm R}$ . The response of the wild-type and various mutant derivative promoters to different amounts of repressor was analysed. The interaction of the repressors, of cro proteins and of RNA polymerase with wild-type and mutant operators, as well as other properties of these proteins, were studied in vitro using purified components. By combining results from various such experiments, a coherent picture has emerged in each case.

Similarities in repressor structures. Like the  $\lambda$  repressor, the P22 and 434 repressors are folded into two structural domains which can be separated by proteases, including activated recA (refs 11, 33) and J. Anderson and M.P.; J. De Anda and R.S.; and R. Yocum and M.P., unpublished results). The aminoterminal fragments of 434 and P22 repressors bind specifically to their operators (J. Anderson and M.P.; J. De Anda, A.P. and R.S., unpublished results). Although the evidence is inconclusive, it seems that the P22 and 434 repressors must dimerize before binding to their operators  $^{9.34}$ .

The  $\lambda$ , 434 and P22 repressors share extensive homology in their carboxy-terminal regions (refs 35, 36; R. Yocum and M.P., unpublished results). When the sequences are aligned, ~30% of the amino acids are identical. The amino-terminal domains of the three phage repressors (and of the cro protein—see below) show considerably less, but still significant, homology (R.S. R. Yocum, A.P and R. Doolittle, unpublished results). Of particular interest is a conserved Ala-Gly near the middle of each repressor. The recA protease cleaves this bond in all three repressors (ref. 33 and R. Yocum and M.P., unpublished results). We surmise that these homologies reflect, at least in part, structures that are recognized and cleaved by the recA protease to effect phage induction (see ref. 33). We note that a cellular repressor of UV-inducible genes, the product of the lexA gene, is also cleaved by the recA protein; it shares substantial carboxy-terminal homology with the phage repressors and carries an Ala-Gly in or near the recA cleavage site (refs 37, 38 and R. Yocum, R. Brent and M.P., unpublished results).

Similarities in operator structure and repressor binding. Although the  $\lambda$ , 434 and P22  $O_R$ s differ in DNA sequence, they are arranged in a strikingly similar way: each consists of three homologous, partially symmetric repressor binding sites (Fig. 2 and refs 1, 39-41). As in the case of  $\lambda$ , repressor dimers of 434 and P22 do not bind independently to their three operator sites; rather they fill sites  $O_R1$  and  $O_R2$  cooperatively and coordinately<sup>41,42</sup>. In P22, this cooperativity presumably results from protein-protein interactions between carboxy-terminal sequences of adjacently bound repressor dimers, because as with  $\lambda$ , the isolated amino-terminal domains bind specifically but non-cooperatively to the  $O_R$  of P22 (J. De Anda, A.P. and R.S., unpublished results). As for  $\lambda$ , so with 434 and P22: if repressor cannot bind to  $O_R1$  because that site is mutant, the repressors fill sites  $O_R2$  and  $O_R3$  cooperatively<sup>41,42</sup>.

The intrinsic affinity of each phage repressor for its operator sites, together with the cooperative interactions, ensure that for all three phages, repressor binds with the affinity order  $O_R 1 \approx O_R 2 > O_R 3$ . In lysogens of  $\lambda$ , 434 or P22, the repressor level is such that almost all templates bear repressors at  $O_R 1$  and  $O_R 2$  and that  $O_R 3$  is free of repressor in a significant fraction of cells<sup>5,6,41,42</sup>.

Common patterns of gene control by repressor. Repressors bound to  $O_R1$  and  $O_R2$  in both P22 and 434 elicit the same transcriptional response as does  $\lambda$  repressor bound to the corresponding sites. That is, in each case, repressor turns off  $P_R$  and turns on  $P_{RM}$  (refs 6, 41, 42). However, this similarity is deceptive and, indeed puzzling, because the overlaps between the promoters and operators are different in the three cases. For example,  $O_R2$  in P22 is 11 base pairs (bp) closer to the transcriptional start of  $P_{RM}$  than is the  $O_R2$  of  $\lambda$  to its  $P_{RM}$  (Fig. 2). Nevertheless, in P22 as in  $\lambda$  (as well as in 434), repressor bound only to  $O_R2$  activates  $P_{RM}$ . At first glance, this is surprising because, as we have previously described for  $\lambda$ , very small

differences in the position of repressor can qualitatively change the effect on transcription. For example,  $\lambda$  repressor bound to  $O_R2$  alone (a condition achieved with appropriate operator mutants) turns off  $P_R$  and turns on  $P_{RM}$ , even though it is positioned exactly 1 bp closer to the former than the latter. We have argued that this 1-bp difference enables repressor to contact polymerase and aid its binding to one promoter  $(P_{RM})$ , excluding its binding to the other  $(P_R)$ . Nevertheless we believe that in spite of differences in promoter—operator overlap, a common mechanism of positive (as well as of negative) control obtains for  $\lambda$  and P22.

Positive control: In P22 as in  $\lambda$ , a protein-protein contact could be made between the amino-terminal domain of a repressor bound at  $O_R2$  and an RNA polymerase molecule bound at  $P_{RM}$ (see Fig. 3a, c). Moreover, the same region of RNA polymerase (shaded in Fig. 3) plausibly could be contacted in the two cases. This hypothesized site of contact is near a phosphate group which, according to the chemical probe experiments, is closely approached by both repressor at  $O_{\rm R}2$  and polymerase at  $P_{\rm RM}$ (compare Fig. 3b, d). In any case, the spatial relationship of polymerase and repressor differs in the two cases: for P22, repressor (at  $O_R2$ ) and RNA polymerase (at  $P_{RM}$ ) cover different faces of the same two turns of the DNA helix, whereas in  $\lambda$  the molecules are arranged more nearly in tandem. In the case of 434, the distance between  $O_R2$  and  $P_{RM}$  is very close to that for  $\lambda$ , and it is likely that the relationship of repressor at  $O_{\rm R}2$ and polymerase at  $P_{RM}$  is the same for  $\lambda$  and 434 (see Fig. 2). Negative control: Repressor bound to  $O_R1$  and  $O_R2$  excludes binding of RNA polymerase to  $P_R$ , a point readily visualized for the  $\lambda$  case by comparing Fig. 3b and f. 434 and P22 repressors also exclude binding of RNA polymerase to  $P_R$ , but in these cases, different sets of DNA contact points are masked 41,42 As expected from this model nuclease probe experiments (performed with  $\lambda$  and P22) show that binding of RNA polymerase to  $P_R$  and repressor to  $O_R1$  and  $O_R2$  are mutually exclusive  $^{26,42}$ . Moreover, in the case of  $\lambda$ , it has been explicitly shown that repressor bound either to  $O_R1$  or to  $O_R2$  represses

Common mechanism of cro action. Like  $\lambda$ , 434 and P22 also encode cro proteins. The 434 cro protein, roughly the same size as that of  $\lambda$ , has been isolated and partially characterized<sup>43</sup>. It binds specifically to (or near) the 434 operator. Strains bearing mutated 434 and P22 prophage can exist stably in the 'anti-immune' state (see above) in which repressor synthesis is turned off, but cro synthesis persists<sup>30,44</sup>. This suggests, by analogy with  $\lambda$ , that the cro proteins from these phages bind to  $O_R3$  more tightly than to the other two sites in  $O_R$ , and that cro bound to  $O_R3$  would repress  $P_{RM}$  but allow transcription of  $P_R$ .

An intriguing fact has recently emerged from a comparison of the  $\lambda$ , 434 and P22 cro and repressor amino acid sequences (R.S., R. Yocum, A.P. and R. Doolittle, unpublished results). When the cro sequences are aligned with those of the repressor amino-terminal domains, significant homologies are revealed. Some positions are conserved in all six proteins; others are occupied by amino acids of a similar chemical type. The homology between individual cro and repressor sequences is in some cases very strong, and in others, much weaker. For example, repressor and cro from 434 are strikingly similar in sequence (ref. 45 and R. Yocum, unpublished results) whereas λ repressor and  $\lambda$  cro show little obvious homology to one another, a point noted previously by us and others<sup>1,28,35</sup>. In particular, the 10amino acid  $\alpha$  helix of  $\lambda$  cro proposed by Anderson et al.<sup>46</sup> to fit into the major groove of operator DNA shows little homology with the corresponding region of  $\lambda$  repressor. However (as noted above), these regions (identified by homology) are very similar in cro and repressor of 434. It remains to be seen how these similarities and differences in amino-acid sequence contribute to the different order of binding, and hence physiological effects, of the three cro/repressor pairs. In any case, the similarities between the phage repressor and cro sequences suggest a common evolutionary origin for the six regulatory proteins.

### Cooperativity and phage induction

Here we argue that the features that are common to  $\lambda$ , 434 and P22, including the tripartite operator, the various forms of cooperativity and the action of cro, enable the phage to switch from one state (lysogeny) to the another (lytic growth) in response to a transient signal.

Repressor dimerization and cooperative binding of dimers to adjacent sites. Why are two sites,  $O_R1$  and  $O_R2$ , used to mediate the effects of repressor in a lysogen? Why does repressor dimerize and why do two dimers fill sites  $O_R1$  and  $O_R2$  cooperatively? At first glance, it might seem that a stable dimer binding tightly to a single site  $(O_R2)$  would suffice. We believe that the dimerization and subsequent cooperative repressor binding to two adjacent sites ensures tight repression but maintains the system in a state poised to respond dramatically to a rather modest decrease in repressor concentration.

This conclusion is illustrated in part by Fig. 4, which indicates that  $P_R$  repression is a steep function of repressor concentration. This curve was calculated from data describing the binding of repressor to various wild-type and mutant templates in vitro (see Table 1 and Fig. 4 legend). Our measurements and calculations<sup>47</sup> indicate that in a lysogen, the degree of repression of  $P_R$  is at least 99% (see Fig. 4 legend). According to the curve, inactivation of 90% of the repressor would suffice to derepress  $P_R$  to  $\sim 50\%$  of its maximal level. This response is in striking contrast to that produced by a system involving stably oligomeric repressor binding to a single operator site (as exemplified by lac) which maintains an equivalent amount of

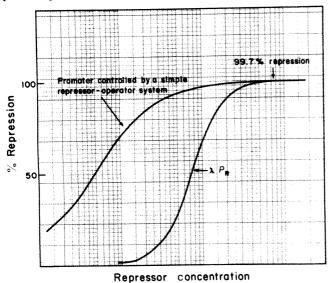

Fig. 4 Theoretical repression curves for  $\lambda P_R$  and a simple repressoroperator system such as lac. The curves show the extent of repression as a function of total repressor concentration. They were calculated as follows.  $\lambda P_R$ : at each total repressor concentration, the concentration of repressor dimers was calculated from the known equilibrium dissociation constant  $(K_D = 2 \times 10^{-8} M)^{10}$ . The distribution of repressor dimers among each of the eight possible states of the operator (Table 1) was calculated from a knowledge of the relative energy of each state using standard methods of statistical thermodynamics<sup>47</sup>. The energies of each of the eight states of Table 1 were deduced from DNA binding studies carried out in vitro<sup>4</sup>. A repressor dimer bound either to  $O_R1$ ,  $O_R2$  or to both sites, will repress  $P_1$ For any repressor dimer concentration, therefore, the fraction of  $O_R$  templates with  $P_R$  repressed is given as the sum of states 1, 2, 4, 5, 6 and 7 from Table 1. Simple repressor-operator system: for comparison we show a theoretical repression curve for the case of a protein (of a stable oligomeric form) binding to a single DNA site (that is, lac repressor binding to its operator). The curve was generated from the simple relation,  $OR/O_T$  $1/(1+K_D/R_T)$  where  $OR/O_T$  is the fraction of operators occupied by a repressor,  $R_T$  being the total repressor concentration, and  $K_D$  is the dissociation constant describing the reaction RO = R + O (ref. 68). The two curves in the figure were aligned at the 99.7% repression point. We believe this to be a minimum estimate of the extent of repression found in a  $\lambda$ lysogen. This value was derived from the knowledge<sup>5</sup> that in a lysogen,  $O_R3$ is  $\sim 20\%$  repressed. According to our calculations, when  $O_R3$  is 20% repressed,  $P_R$  is at least 99.7% repressed. We have no direct way of measuring accurately the extent of repression actually found in a lysogen. However, we know that the extent of repression of the lac operon in vivo is ~99.9%

Table 1 Eight possible configurations of repressor at  $O_R$ 

	Configuration			Free-energy	Total free energy
State	$O_{R}3$	$O_R2$	$O_R1$	contributions	(kcal mol <sup>-1</sup> )
0				(reference state)	0
1			+	$\Delta G_1$	-11.6
2		+		$\Delta G_2$	-10.1
3	+			$\Delta G_3$	-10.1

+ Indicates that the corresponding site is occupied by a repressor dimer. The free energies of each state (relative to the reference state) are listed.  $\Delta G_1$ ,  $\Delta G_2$  and  $\Delta G_3$  are the intrinsic interaction energies of repressor dimers binding to each of the three sites.  $\Delta G_{12}$  is the net interaction energy supplied by the cooperative interaction between a repressor dimer at  $O_R1$  and one at  $O_R2$ .  $\Delta G_{23}$  is similarly defined. These values, measured in 'physiological conditions' (200 mM KCl, 37 °C) are  $\Delta G_1 = -11.6$  kcal mol<sup>-1</sup>,  $\Delta G_2 = \Delta G_3 = -10.1$  kcal mol<sup>-1</sup>,  $\Delta G_{12} = \Delta G_{23} = -2.0$  kcal mol<sup>-1</sup> (ref. 4) (see Fig. 4 legend).

repression (see Fig. 4). In this case, 50% induction requires inactivation of a much larger fraction of repressor (>99%), and inactivation of 90% of the repressor would result in only  $\sim 3\%$  derepression and thus induction. There is evidence that inactivation of 90% of the  $\lambda$  repressor in a lysogen produces highly efficient induction<sup>24</sup>. Both repressor dimerization and cooperative binding to  $O_R1$  and  $O_R2$  contribute to the steep slope of Fig. 4 (ref. 47).

 $P_{\rm RM}$  activation and the action of cro protein. Once  $P_{\rm R}$  of a prophage is derepressed, why does the phage not simply reestablish repression as the inducing signal decays? We believe that the dependence of  $P_{\rm RM}$  activity on bound repressor and the action of cro prevent the re-establishment of lysogeny and promote lytic growth. As repressor present in a lysogen is inactivated, it vacates  $O_{\rm R}$ . A template lacking a repressor at  $O_{\rm R}2$  no longer directs synthesis of repressor efficiently, and thus the rate of repressor synthesis declines. At the same time, cro is synthesized, and by binding first to  $O_{\rm R}3$ , turns off repressor synthesis and promotes lytic growth.

Thus in summary the three related phages,  $\lambda$ , 434 and P22, encode specific repressor and cro proteins that interact in each case with a key regulatory sequence, termed the right operator. We find that despite detailed differences in mechanism, in each case repressor in a lysogen binds cooperatively to the tripartite operator, turning off lytic genes and stimulating transcription of its own gene. We have argued that a common molecular mechanism of positive and negative control obtains in each case, despite differences in operator-promoter overlap. Moreover, we argue that the common features of repressor action, including in each case its cooperative interaction with a tripartite operator, have been maintained to ensure the switch from lysogenic to lytic growth. Thus, in a lysogen, repressor is bound predominantly to  $O_R1$  and to  $O_R2$ , thereby repressing  $P_R$  and activating  $P_{RM}$ ; to a lesser extent repressor is bound to  $O_R3$ , thereby turning down repressor synthesis.

The lysogenic state is stably inherited; lysogens spontaneously induce only about once per  $10^5$  generations. On exposure of lysogens to inducer, cleavage of repressor commences. A 5-10-fold drop in repressor level triggers a dramatic change of state as  $O_{\rm R}1$  and  $O_{\rm R}2$  are vacated: because repressor synthesis depends on autogenous stimulation, its rate of synthesis decays rapidly. Moreover, induction of  $P_{\rm R}$  results in synthesis of cro, a protein required for lytic growth, which binds to  $O_{\rm R}3$ , turns off  $P_{\rm RM}$ , and thereby completes the switch to lytic growth. The various forms of protein-protein interaction involving repressor ensure stability of the lysogen but permit  $P_{\rm R}$  to begin functioning in response to a moderate decrease in repressor level.

#### **Further considerations**

**Role and positioning of O\_R 3.** We have explained that the two sites  $O_R 1$  and  $O_R 2$  and their interaction serve an important

biological function that could not be met by a single repressor binding site. We have also described a role for  $O_R3$ , that is, turning off repressor synthesis by ero and thus promoting lytic growth. We now suggest two additional functions for  $O_R3$ .

First, repressor can also bind to  $O_R3$  and turn off transcription of its own gene. We have found that in lysogens,  $O_R3$  of  $\lambda$  is  $\sim 20\%$  occupied (and  $O_R3$  of P22 slightly more), whereas sites  $O_R1$  and  $O_R2$  in both  $\lambda$  and P22 lysogens are almost completely filled 5.6,41,42. The negative autogenous control mediated by repressor binding to  $O_R3$  should help to maintain constant repressor concentrations, but apparently the effect is not dramatic. For example, we have found that a fivefold increase in  $\lambda$  repressor concentration decreases the rate of repressor synthesis only by  $\sim 20\%$  (ref. 5); we do not know whether this response is physiologically important. Perhaps slight decreases in repressor levels that otherwise might trigger induction are compensated for by increased repressor synthesis as  $O_R3$  is vacated. It is possible that negative autogenous control in 434 is more extensive than in the other two phages (see ref. 9), but our understanding of the situation is incomplete.

Second, as we have mentioned elsewhere<sup>1</sup>, we belive that  $O_R3$  helps to prevent the accumulation of  $\lambda$  virulent mutants—variants that grow lytically (and only lytically) on lysogenic as well as on non-lysogenic cells, and thereby destroy the lysogenic system. A requirement for virulence is that transcription from  $P_R$  proceed efficiently in the presence of repressor at the concentration found in a lysogen. In general<sup>48</sup>, two sites in  $O_R$  must be mutant, either one in  $O_R1$  and another in  $O_R2$  or one in  $O_R1$  and another in  $O_R3$ .

We understand this requirement for two mutations to be as follows. (1) If a phage acquires a mutation in  $O_R 1$  alone,  $P_R$  will nevertheless be repressed because the cooperative interaction between repressor dimers at  $O_R2$  and  $O_R3$  ensures that  $O_R2$  will be occupied. Addition of a second mutation in  $O_R2$  or in  $O_R3$  is necessary for  $P_R$  to escape repression. This hypothesized role of  $O_{\rm R}3$  (but not the first two described above) requires that  $O_{\rm R}3$  be positioned close to  $O_R2$  so that the necessary cooperative interaction can occur. (2) If a phage acquires a mutation in  $O_R 2$ , the high intrinsic affinity of O<sub>R</sub>1 for repressor nevertheless ensures that  $P_R$  will be repressed, and an additional mutation in  $O_{\rm R}1$  is required. Thus, the pattern of intrinsic affinities and alternate cooperative repressor binding to the three sites imposes the requirement that two mutations, rather than one, must be accumulated for  $O_R$  to escape repression. Furthermore, phage that have acquired one operator mutation (in either  $O_R 1$ or  $O_R 2$ ) cannot lysogenize (because occupancy of  $O_R 1$  and  $O_R 2$ , but not of  $O_R3$ , is required for lysogeny) and such phage are thereby presumably at a selective disadvantage compared with wild-type.

Efficiencies of  $\lambda$  and lac repressor. The affinity  $(K_{\rm D})$  of a  $\lambda$  repressor dimer for  $O_{\rm R}1$  on a wild-type template in 'physiological conditions' (37 °C, 0.2 M KCl) is  $3 \times 10^{-9}$  M (refs 4, 10, 13). The other, well-studied repressor, the lac repressor, binds to its operator much more tightly in these conditions  $(K_{\rm D}=10^{-12}\,{\rm M})^{49}$ . Nevertheless, as argued in the text, we believe that  $\lambda$  repressor in a lysogen turns off  $P_{\rm R}$  about as efficiently as lac repressor turns off the lac promoter (repression  $\geq 99.7\%$ ).

The  $\lambda$  repressor achieves a similar degree of repression despite a lower binding constant because of the following factors. First, the  $\lambda$  repressor is present at 5-10-fold higher concentration in a cell than is lac repressor. (There are ~200 monomers of  $\lambda$  repressor  $(10^{-7} \, \mathrm{M})$  in a lysogen<sup>8,9,24,50</sup> and the  $K_D$  describing dimer formation is  $2 \times 10^{-8} \, \mathrm{M}$  (ref. 10), whereas the concentration of lac repressor stable species (tetramer) is 10-20 molecules per cell<sup>51,52</sup>.) Second, the affinity of lac repressor for non-operator DNA may decrease its effective concentration in E. coli relative to  $\lambda$  repressor. For lac repressor, the ratio of affinities for nonspecific to operator DNA is  $\sim 10^{-8}$  (ref. 49). The binding constant of lac repressor for random 20-bp non-operator sequences  $(10^{-4} \, \mathrm{M})$ , taken with the

total concentration of such sequences in E. coli  $(10^{-2} \,\mathrm{M})$ . suggests that an appreciable fraction of repressor is sequestered on nonspecific DNA<sup>49,53</sup>. Linn and Riggs<sup>49</sup> have argued that this effectively weakens the binding constant of lac repressor by two orders of magnitude. We know that for  $\lambda$  repressor, the ratio of nonspecific to specific DNA binding is  $\sim 10^{-8} \,\mathrm{M}$  at low salt and low temperature 10. Assuming that this ratio is the same in 'physiological conditions' (see above), we estimate that little or none of the  $\lambda$  repressor in a lysogen is bound to non-operator DNA. Third, a consequence of repressor dimerization and of cooperative binding of repressors to  $O_R1$  and  $O_R2$ (see Fig. 4) is that 99.7% repression is reached when the concentration of repressor is ~12-fold above that needed to fill half the sites (that is, the apparent  $K_D$ ), and this is the amount of repressor found in a lysogen. In the lac case, this degree of repression is achieved only when the concentration of repressor exceeds the  $K_D$  300-fold.

**Positive control.** We have described a particular mechanism whereby the phage repressors mediate positive control of transcription in  $\lambda$ . Note that we have paid little attention to an alternative mechanism, which we now discuss.

It is conceivable that RNA polymerase bound to the strong promoter,  $P_{\rm R}$ , would exclude binding of polymerase to the weak promoter,  $P_{\rm RM}$ , and that the role of repressor in positive control is to prevent binding of polymerase to  $P_{\rm R}$ .

This model deserves serious consideration for  $\lambda$ , 434 and P22 because in each case the two promoters,  $P_R$  and  $P_{RM}$ , are adjacent. A series of experiments argues strongly that in  $\lambda$ , this model is excluded. Polymerase bound at  $\lambda$   $P_R$  has little inhibitory effect on binding of polymerase to  $P_{RM}$ , and removing  $P_R$  does not activate  $P_{RM}^{}$ . In the case of P22 and 434,  $P_R$  and  $P_{RM}^{}$  are significantly closer than in  $\lambda$ , and although we have no definitive evidence, we believe it likely that in each case polymerase bound to one inhibits binding of polymerase to the other  $^{41,42}$ . Nevertheless, deletion of  $P_R^{}$  of P22 does not activate its  $P_{RM}^{}$ : rather, as in  $\lambda$ , repressor must be bound to the DNA for  $P_R^{}$  stimulation. Thus, in  $\lambda$ , the repressor provides an essential contact with polymerase at  $P_{RM}^{}$ , whereas it is likely that in P22 and 434, the repressor both excludes a competing polymerase at  $P_{RM}^{}$ .

Analogy with haemoglobin. A haemoglobin tetramer bearing a bound oxygen has a higher affinity for oxygen than does a haemoglobin tetramer bearing no oxygen<sup>54</sup>. As a result, a small change in oxygen pressure can cause a dramatic change in oxygen binding to haemoglobin. The interaction of the  $\lambda$  operators with  $\lambda$  repressor and of haemoglobin with oxygen are formally analogous. As shown in Table 1, the energy of interaction of repressor for  $O_R1$  alone is -11.6 kcal mol<sup>-1</sup>, and that for  $O_R2$  alone is -10.1 kcal mol<sup>-1</sup>. The net interaction energy between adjacent repressor molecules is -2 kcal mol<sup>-1</sup>, which means that the effective energy of binding to the second site on a wild-type template is -12.1 kcal mol<sup>-1</sup>. Thus, an operator containing a bound repressor has a higher affinity for a second repressor than does an operator bearing no repressor. As a consequence, small changes in repressor concentration can have a dramatic effect on repressor binding to the operator (see Fig. 4). An important difference in the analyses of  $\lambda$  and haemoglobin is that in the latter case, one must measure the total amount of ligand (oxygen) bound. In contrast, for  $\lambda$ , we can quantitate binding of the ligand (repressor) to each of the three sites in the operator. This greatly simplifies analysis of mechanism (see ref. 47).

Other cases. Interactions between adjacent DNA-bound proteins probably also play an important part in both prokaryotic (see, for example, refs 70-73) and in eukaryotic gene regulation. For example, transcription of the SV40 early genes (including that which encodes T antigen) is repressed by the T antigen<sup>55-59</sup>. This protein binds to three sites near the early transcription start-point. Binding of the purified protein to the middle site is enhanced by previous binding to the first<sup>60</sup>. There is evidence<sup>60</sup> that this cooperative binding is mediated by pro-

tein-protein interactions between adjacent T-antigen molecules.

In another case, transcription of the 5S gene of Xenopus in partially fractionated oocyte extracts is stimulated by a protein that binds specifically to a site within the gene<sup>61</sup>. One interpretation of the experiments of Sakonju et al.<sup>61,62</sup> is that the function of the stimulatory factor is to promote binding of RNA polymerase to the (relatively nonspecific) adjacent DNA sequence.

In prokaryotes, as well as eukaryotes, transient signals can induce epigenetic changes which are then stably inherited<sup>63,6</sup> The phage cases we have analysed demonstrate one molecular mechanism for ensuring such a response. More generally, it is

plausible that at one or more stages during the development of higher organisms, differences between daughter cells depend on the asymmetric distribution of cytoplasmic determinants formerly present in the parental cell. Our analysis of the  $\lambda$  case shows how a relatively small (<10-fold) change in such factors can cause a drastic epigenetic change.

## Oscillatory zoning: a pathological case of crystal growth

## Claude J. Allègre, Ariel Provost & Claude Jaupart

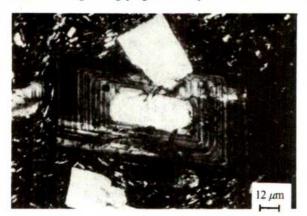

Laboratoire de Géochimie et Cosmochimie, Institut de Physique du Globe et Département des Sciences de la Terre, 4 place Jussieu, 75230 Paris Cédex 05, France

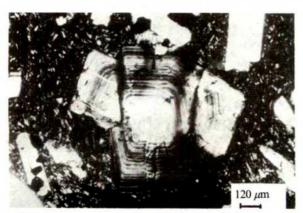

A new theory of oscillatory zoning in naturally grown plagioclase crystals is presented. This describes explicitly the coupling between the interface kinetics and the diffusion of chemical species in the melt. The crystal growth rate R responds with a finite delay time to concentration changes at the interface. Thus the growth rate cannot be simply some function of the supersaturation. Oscillatory zoning occurs when growth rate is low. This theory accounts for the absence or extreme rareness of oscillatory zoned plagioclase crystals in laboratory growth experiments.

PLAGIOCLASES are usually compositionally, and thus optically, zoned. On large scale irregular and abrupt changes in composition (stepped zoning) are often superimposed almost periodic variations (oscillatory zoning). This 'mineral stratigraphy' has long interested petrologists because it offers a potentially useful record of environment changes during crystallization<sup>1-7</sup>. It is generally accepted that stepped zoning is created by physicochemical variations in the magma whereas oscillatory zoning is a local phenomenon due to crystal growth processes. However, no quantitative analytical theory has been developed, and the available theories do not explain why the plagioclase–melt system is one of the few natural systems to exhibit this phenomenon.

Zoning patterns in plagioclase crystals have been described elsewhere <sup>1-4,8-12</sup>. Typical oscillatory zoning characteristics are illustrated in Fig. 1: oscillations occur as groups separated by abrupt changes. The sequence from inner to outer groups generally displays a trend towards greater albite content. The oscillation width is almost constant for a given group but may vary from group to group in the 10–30 µm range. Each concentration peak has a characteristic shape, usually a smooth Ab increasing flank followed by a steep Ab decreasing flank, although there may be no asymmetry in some cases<sup>7</sup>.

We do not discuss the arguments based on constitutional supersaturation which favour an 'internal' origin for oscillatory zoning (see, for example, refs 4, 6 and 7) but from an observational point of view, it is remarkable that no inter-crystal correlation of oscillation bands has been reported<sup>13</sup>. Several authors<sup>6,14,15</sup> have demonstrated the existence of concentration gradients before growing plagioclase crystals and stressed the

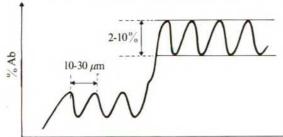

Fig. 1 a, Two examples of oscillatory zoning in plagioclase crystals. Samples are basaltic andesites from the Colima volcano (Mexico) (photographs provided by C. Bollinger). b, Cross-section of an oscillatory zoned portion of a plagioclase crystal: schematic plot of composition versus distance (from refs 6, 7).

Distance from core

fundamental role of chemical diffusion. There is clear evidence for a near-crystal layer enriched in elements with solid-liquid partition coefficients smaller than 1 (Mg, Fe, Si, Na)<sup>6</sup>.

The phenomena which occur during crystallization from a liquid can be broadly classified as interactions between three important variables: (1) the crystallographic features of the growing crystal and the associated effects on the interface kinetics, (2) the temperature distribution in the liquid, (3) the distribution of elements in the liquid.

In the present context, heat diffusion is much more efficient than chemical diffusion and temperature is not a limiting variable for the low growth rates considered. The competitive character of interface kinetics and chemical diffusion alone does not explain the phenomenon of oscillatory zoning. Consider a newly nucleated crystal: there is no diffusion layer in front of the interface, and growth begins with a fast increasing Ab concentration. Eventually, a steady-state regime should be reached with equal growth and diffusion rates. Kinetic effects may explain why this may not occur.

#### Equations for plagioclase growth

We now consider the equations which govern the interface kinetics—chemical diffusion interaction. Assuming a flat interface, we consider a coordinate system which moves with the crystal surface, and restrict the discussion to one-dimension, two-component fickian diffusion for simplicity. Strictly, our single independent component is that eigen-vector of the diffusion coefficient matrix which is associated with its lowest eigenvalue D, but as it is comparatively Si-rich and Al-poor, it will be labelled 'albite' for clarity. Albite concentration in the melt at a distance x from the interface, C(x, t), is governed by:

$$\frac{\partial C}{\partial t} = D \frac{\partial^2 C}{\partial x^2} + R \frac{\partial C}{\partial x}$$
 (1)

where R(t) is the crystal growth rate. If slower solid diffusion is neglected, mass balance at the interface reads:

$$R(C_0 - C_s) = -D \frac{\partial C}{\partial x}\Big|_{x=0}$$
 (2)

where  $C_0(t) = C(0, t)$  and  $C_s(t)$  stand for liquid and solid Ab concentrations at the interface. The second boundary condition is a 'far away fixed concentration' condition:

$$C(x_1, t) = C_{\rm m} \tag{3}$$

where  $x_1$  is the distance at which mean magma Ab concentration  $C_m$  is maintained. For simplicity,  $x_1$  is taken as infinite throughout.

For given initial conditions, two more boundary conditions must be specified. In the limiting case of instantaneous interface kinetics (when growth is controlled by diffusion in the vicinity of the interface), these are the thermostatic equations  $C_0 = C_L$  and  $C_s = C_S$ , where  $C_L$  and  $C_S$  are the liquidus and solidus Ab concentrations. In the other limiting case of instantaneous diffusion (interface kinetics controlled growth), equations (1) and (2) degenerate and  $C_S$  and R are functions of  $C_0 = C_m$ . In the more intricate intermediate situations, the two required conditions must link  $C_S$  and R to  $C_0$  and t, but there are few constraints from experiments or theory (see refs 16 and 17 for discussions). There is, however, some experimental evidence that the partition coefficient  $K = C_S/C_0$  remains approximately constant even when R changes by an order of magnitude 18.

Most theories explicitly or implicitly state that  $C_s$  and R are single-valued functions of  $C_0$ , as they are in the limiting case of instantaneous diffusion (well-stirred solutions or melts). But, complicated though these functions may be, equations (1) (2) and (3) cannot produce oscillations, because of the presence of only a first-order time derivative (this is at variance with mechanical or electrical oscillators for which a second-order or two coupled first-order differential equations are involved).

Bottinga et al.<sup>6</sup> and Sibley et al<sup>7</sup> suggest a hysteresis behaviour for R. Oscillatory zoning requires a jump from very slow growth

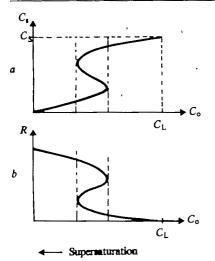

Fig. 2 According to Haase et al.  $^{21}$ , the albite content  $C_s(a)$  of a growing plagioclase crystal and its growth rate R(b) may be triple-valued functions of  $C_0$  (the albite content at interface) over a finite interval of supersaturations. This figure is not drawn to scale.

to no growth, which in turn has to wait for a new nucleation step. But their discussions offer no clear explanation for such a jump and rely on an 'interface diffuseness' concept<sup>19</sup> which seems questionable<sup>20</sup>.

The kinetic theory proposed by Haase et al.  $^{21}$  considers  $C_s$  and R as functions of  $C_0$  and  $C_s$ , then predicts that  $C_s$  and thus R are tripled-valued functions of  $C_0$  on a certain interval of  $C_0$  values (Fig. 2). They argue that  $C_s$  and R oscillate between the lowest and the uppermost branches (the middle one being clearly unstable with respect to chemical diffusion). But they do not explain why R and  $C_s$  stay on a given branch as long as possible, nor does the theory describe the necessary up and down jumps. This points to a failure of the kinetic model which may be modified either by considering a discontinuity (analogous to phase changes or shock waves) or by adding a dynamic term (such as finite response time for one variable). Only the latter may lead to an oscillatory behaviour.

The important question is therefore: does the growth rate respond immediately to the changing composition? The advance of a solid-liquid interface is known, both theoretically  $^{22,23}$  and experimentally  $^{24}$ , to depend critically on the detailed structure of the interface on the molecular scale. As site formation is a probabilistic process, there will be a delay between a change in  $C_0$  and a change in R. A plausible equation for R is thus:

$$\tau \frac{\mathrm{d}R}{\mathrm{d}t} + R = \Re(C_0) \tag{4}$$

where  $\tau$ , the characteristic time for structural rearrangement, is taken as constant for simplicity. Samoylovich<sup>25</sup> proposed a similar equation for the advance of a crystallization front with prescribed thermal gradients at the boundaries of the crystallizing region.

If  $\tau$  is zero or steady-state obtains, equation (4) reduces to  $R = \Re(C_0)$ , that is the growth rate is some function of the supersaturation which may be determined by laboratory experiments. According to what is known of nucleation and growth mechanisms, the positive function  $\Re(C_0)$  must vanish for  $C_0 = C_L$  and increase with decreasing  $C_0$  (at least for moderate supersaturations). Some indication of its magnitude and sensitivity to concentrations and temperature is provided by data from ref. 15. The essence of our analysis lies in equation (4) where we suggest that R should be considered as the solution of a differential rather than algebraic equation. Although this may represent a reasonable approach to growth mechanisms, it should be regarded as phenomenological. We show next that the proposed coupling between R and  $C_0$  results in an oscillatory behaviour consistent with observations.

### A quantitative model

Before dealing with equations (1) and (4), we describe qualitatively what happens during a typical episode of crystal growth. At time t=0, growth starts in a regime controlled by the

interface kinetics. Initially the concentration profile in the melt phase is flat and  $C_0$ , the concentration at the interface, is equal to  $C_{\rm m}$ . As growth proceeds, a concentration boundary layer develops ahead of the crystal and growth becomes progressively diffusion controlled. As time increases,  $C_0$  tends to  $C_L$  and the concentration profile tends asymptotically to that described by the boundary condition  $C_0 = C_L$  (ref. 26, p. 146). Therefore, the boundary layer thickness  $\delta$  behaves asymptotically as  $\sqrt{t}$ , and R behaves as  $1/\sqrt{t}$ . In this limit, the function  $\Re(C_0)$  in equation (4) may be approximated by an equation such as:

$$\Re(C_0) = Q(C_L - C_0)^* \tag{5}$$

This general form of  $C_0$  and R is sketched in Fig. 3. Throughout this evolution, the concentration boundary layer thickness  $\delta$  increases as the crystal evolves towards higher and higher albite concentrations.

The situation is more complex for an oscillatory growing crystal. However, the observations show that the oscillations are of small amplitude and are superimposed on a regular evolution which follows along the lines described above. This will lead us to write the general solution as the sum of a regular slowly-varying solution and a perturbation of small amplitude. A remarkable aspect of the governing equations is that a qualitative knowledge of the regular solution enables us to predict the behaviour of the perturbations. We integrate equation (1) and obtain:

$$\int_{0}^{\infty} \frac{\partial C}{\partial t} dx = -D \frac{\partial C}{\partial x} \Big|_{x=0} + R(C_{m} - C_{0})$$
 (6)

We define a diffusion width  $\xi(t)$ , which is a measure of the thickness of the concentration boundary layer, as:

$$\int_{0}^{\infty} (C - C_{\mathbf{m}}) \, \mathrm{d}x = \xi (C_{0} - C_{\mathbf{m}}) \tag{7}$$

Using equation (7) and boundary conditions (2), equation (6) may be written as:

$$\frac{\mathrm{d}}{\mathrm{d}t} \left[ \xi (C_0 - C_{\mathbf{m}}) \right] = R(C_{\mathbf{m}} - KC_0) \tag{8}$$

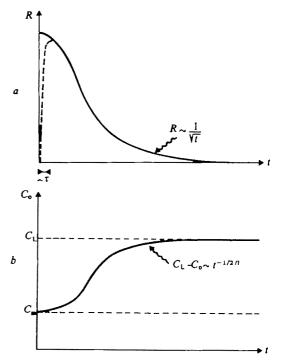

Fig. 3 Plots of the growth rate R(a) and the albite content of the melt at the interface  $C_0(b)$  against time for a typical episode of crystal growth. When the conditions for oscillatory zoning are not fulfilled, it makes little difference whether there is a delayed response of the growth rate (dashed line in a) or not (solid line). n in b is the same as in equation (5).

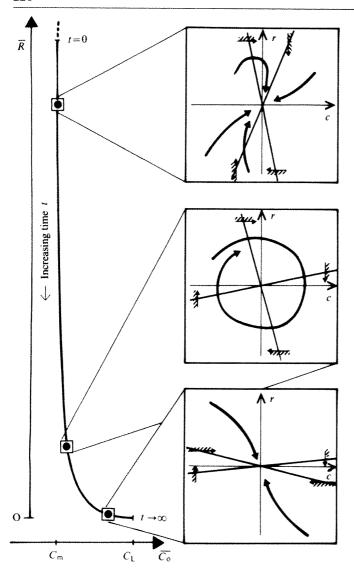

Fig. 4 Phase-plane representation of the solution  $\{R, C_0\}$ . The heavy curve on the left represents the evolution of the quasistationary regular solution  $\{\bar{R}, \overline{C_0}\}$ . Superimposed on that solution is a perturbation  $\{r, c\}$  whose evolution with respect to the regular solution is shown in the three insets at three different stages of growth. In the insets, straight lines represent the isoclines dc/dt = 0 (equation (12)) and dr/dt = 0 (equation (13)), and arrows represent tangents to the evolution curves. We predict the perturbation  $\{r, c\}$  to be rapidly and monotonically flattened out at both the beginning (upper inset) and the end (lower inset), but to exhibit damped oscillations (middle inset) over a finite time interval.

We now write the full solution  $\{R, C_0\}$  as the sum of a slowly-varying regular solution  $\{\overline{R}, \overline{C_0}\}$  and a perturbation of small amplitude  $\{r, c\}$ :

$$R = \overline{R} + r, \qquad C_0 = \overline{C_0} + c \tag{9}$$

The regular solution is described by the following equations:

$$\frac{\mathrm{d}}{\mathrm{d}t} \left[ \xi (\overline{C_0} - C_{\mathrm{m}}) \right] = \bar{R} (C_{\mathrm{m}} - K \overline{C_0}) \tag{10}$$

and

$$\tau \frac{\mathrm{d}\bar{R}}{\mathrm{d}t} + \bar{R} = \Re(\overline{C_0}) \tag{11}$$

We assume next that  $\xi$  has the same value for both the full and the regular solution. This is not strictly valid for any kind of perturbation and essentially depends on the characteristic frequency of the oscillation when it exists. The perturbation is associated with a 'penetration depth' which increases as the

oscillation frequency decreases. In other words, the above assumption may be wrong if the oscillatory zoning period is greater than the characteristic time for crystal growth. Clearly, however, the zoning wavelength is much smaller than typical crystal dimensions. Neglecting second-order terms, we get:

$$\xi \frac{\mathrm{d}c}{\mathrm{d}t} + c \frac{\mathrm{d}\xi}{\mathrm{d}t} = \bar{R}(-Kc) + r(C_{\mathrm{m}} - K\overline{C_{0}})$$
 (12)

and

$$\tau \frac{\mathrm{d}r}{\mathrm{d}t} + r = -\frac{\rho}{C_0}c\tag{13}$$

with

$$\rho = -\overline{C_0} \frac{\mathrm{d}\mathcal{R}}{\mathrm{d}C_0} \bigg|_{C_0 = \overline{C_0}} \tag{14}$$

where the sign has been chosen so that  $\rho$  is positive, as  $\mathcal{R}$  is a decreasing function of  $C_0$ .

Equations (12) and (13) are the two perturbation equations to be solved. They are written with  $\bar{R}$  and  $\bar{C}_0$  as parameters and thus describe the perturbations r and c with respect to the quasi-stationary evolution of the system.

The system can be described qualitatively in the (R, C) phase plane (Fig. 4). There are two general types of trajectories in this plane: either a direct convergence or a spiral towards the regular point  $\{\bar{R}, \overline{C_0}\}$ . In terms of growth behaviour, this means either an ordinary convergence to the regular solution (normal growth) or damped oscillations around mean values  $(\bar{R}, \overline{C_0})$  (oscillatory zoning). These two types of behaviour are possible in different areas of the (R, C) plane and thus at different stages of growth.

We now discuss the system in a more quantitative way. The solutions  $\{r, c\}$  of equations (12) and (13) represent either an exponential decay or damped sinusoidal oscillations depending on the sign of the discriminant:

$$\Delta = \left[\frac{1}{\tau} - \frac{1}{\xi} \left( K\bar{R} + \frac{\mathrm{d}\xi}{\mathrm{d}t} \right) \right]^2 - \frac{4\rho}{\xi\tau} \left( \frac{C_{\mathrm{m}}}{\bar{C}_0} - K \right) \tag{15}$$

As K is <1, quantity  $((C_m/\overline{C_0})-K)$  is positive when growth begins  $(\overline{C_0}=C_m)$  and remains positive if  $C_m$  is greater than  $C_S$  (we do not consider the 'hypersaturation' case  $C_m < C_S$ , which is more complex). As growth proceeds,  $\overline{R}$  and  $d\xi/dt$  decrease while  $\xi$  increases from 0 to  $\infty$ . Therefore, the term in brackets in equation (15) increases monotonously from  $-\infty$  to  $1/\tau$ , passing through zero when:

$$\xi = \tau \left( K\bar{R} + \frac{\mathrm{d}\xi}{\mathrm{d}t} \right) \tag{16}$$

The discriminant is thus positive when growth begins, becomes negative, and then positive again. This shows that oscillatory behaviour will happen at some intermediate stage of the crystal history (Fig. 4). The time  $\hat{i}$  when equation (16) is verified marks the transition from the initial growth regime when growth rate is

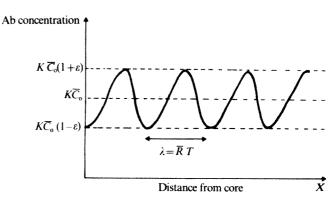

Fig. 5 When the required conditions are met (see text), the perturbation equations result in almost undamped, dissymmetric oscillations in the concentration profile.

essentially determined by the interface kinetics to the final regime when chemical diffusion is the main limiting factor.

However, oscillatory zoning will be detectable only if damping is not too large. The damping coefficient k is defined simply as the ratio of the concentration amplitude from one cycle to the next: k reaches a minimum  $\hat{k}$  at a time close to  $\hat{i}$  defined above. We find that damping is small ( $\hat{k}$  close to unity) when at that time  $\bar{R}/\rho$  is much lower than ( $(C_m/KC_0)-1$ ). As shown by equation (14), this means a high sensitivity of the crystal interface to concentration changes. Consider, for example, equation (5) for  $\Re(C_0)$ . This yields:

$$\frac{\bar{R}}{\rho} = \frac{1}{n} \left( \frac{C_L}{\overline{C_0}} - 1 \right). \tag{17}$$

In this simplified case, oscillatory zoning is certainly detectable for very weak supersaturations as the low damping condition is fulfilled throughout the crystallization sequence.

Furthermore, a long oscillatory episode requires a large value for  $\tau$ . This critical parameter is a measure of the difficulty of rearranging the crystal surface when composition changes. For the plagioclase system, the excess free energy of mixing exhibits large variations in the range  $An_{30} - An_{90}$  because of a complex substitution process due to a transition between a disordered 7 Å and an ordered 14 Å crystal framework (ref. 25, p. 135).

In these conditions, low amplitude, almost undamped, oscillatory zoning is described by:

$$C_{\rm s}(t) = K\bar{C}_0 (1 + \varepsilon \sin \omega t)$$

compared with interface position:

$$X(t) = X(0) + \bar{R}t + \varepsilon \frac{\rho}{\tau \omega^2} \sin \omega t$$
 (18)

where  $\varepsilon$  is the perturbation amplitude. Albite concentration is thus a dissymmetric periodic function of distance X, decreasing more abruptly than it rises (Fig. 5), in agreement with observations<sup>6.7</sup>. The higher the perturbation amplitude  $\varepsilon$ , the more pronounced the dissymmetry.

The above discussion has clarified the conditions for oscillatory behaviour, which seems to be a delicate phenomenon most likely when growth rates are small. We now give numerical estimates for the various parameters.

Equation (1) may be approximated by:

$$D\frac{\partial^2 \bar{C}}{\partial x^2} + \bar{R}\frac{\partial \bar{C}}{\partial x} = 0 \quad \text{in a region } x < x_0 \text{ (close to the interface)}$$

and by

$$D\frac{\partial^2 C}{\partial x^2} = \frac{\partial C}{\partial t}$$
 in a region  $x > x_0$  (far from the interface)

This shows that a reasonable approximation to the concentration profile close to the interface is:

$$\bar{C} = C_{\rm m} + (\bar{C}_0 - C_{\rm m}) \cdot \exp\left(-\frac{\bar{R}}{D} \cdot x\right)$$

Thus  $D/\bar{R}$  is a reasonable estimate for  $\xi$ . We now summarize the quantitative aspects of our theory. We denote by T the oscillation period. The zoning wavelength  $\lambda$  is equal to  $\bar{R}T$ . The damping factor k is taken as  $\hat{k} = \exp{(T/\tau)}$  and small damping implies that ratio  $T/\tau$  is small. This leads to the constraint:

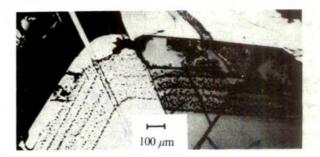

$$\tau \left( K\bar{R} + \frac{\mathrm{d}\xi}{\mathrm{d}t} \right) \simeq \xi \simeq \frac{D}{\bar{R}}$$

Making the further approximation that  $d\xi/dt \ll \bar{R}$ , we obtain the following set of conditions:

$$\lambda = \bar{R}T \simeq 10 \ \mu \text{m}; \quad \bar{R}^2 \tau \simeq \frac{D}{K} \simeq 10^{-8} \ \text{cm}^2 \ \text{s}^{-1} \quad (\text{refs 6, 28})$$

and  $T/\tau$  small (<0.1, say).

The numerical analysis requires a value for the growth rate in realistic conditions. The only measurements available are those

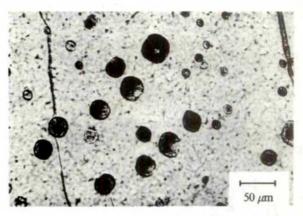

Fig. 6 Rounded glassy inclusions within two different oscillatory zoned plagioclases from North Atlantic tholeittic basalts. Note that, despite the presence of inclusions, oscillatory zones remain remarkably straight and parallel (photographs from ref. 12).

of Lofgren<sup>15</sup> who made plagioclase growth experiments at comparatively low temperatures (800–1,000 °C) and over rather short times (between 10 and 70 h). Taking, for example, a value of 10<sup>-7</sup> cm s<sup>-1</sup>, a value actually measured by Lofgren<sup>15</sup>, we obtain:

$$\tau = 10^6 \,\text{s}$$
 and  $T/\tau = \ln k = 10^{-2}$ 

A value of  $10^{-6} \,\mathrm{cm}\,\mathrm{s}^{-1}$  for the growth rate would yield the following estimates:

$$\tau = 10^5 \, \text{s}$$
 and  $T/\tau = 0.1$ 

The characteristic time  $\tau$  remains poorly constrained but is probably quite large. It may depend on the degree of supersaturation and the estimates quoted above are only valid in the low supersaturation limit.

#### Discussion

Competition between chemical diffusion and interface kinetics should affect all crystals which grow from a melt which is not pure. Delayed response of the growth rate to concentration changes should also be universal. The growth equations predict an episode of oscillatory zoning for all systems provided that the supersaturation is not too large  $(C_s < C_m < C_L)$ . This may seem strange as oscillatory zoning seems to be the exception rather than the rule. Of course, equation (4) is only one way that a time delay could express itself but the explanation is more likely to lie in the numerical values of the characteristic parameters involved in practical situations. For a system in given (Cm, temperature) conditions, oscillatory behaviour is predicted over a certain interval  $\Delta t$  around a time  $\hat{t}$  which marks the transition between interface- and diffusion-controlled growth. For most systems this transition happens much too early or much too late to be detected practically with the result that these systems are classified as interface- or diffusion-controlled. Also  $\Delta t$  must be large enough for oscillations to occur on a measurable crystal length. The oscillation period T must be small enough for the transition episode to include a reasonable number of oscillations and large enough for the zonations, of wavelength  $\lambda = \bar{R}T$ , not to be erased by subsequent solid diffusion. A precise

investigation of these conditions requires a quantitative analysis of the regular solution  $\{\vec{R}(t), \overline{C_0}(t)\}\$  which is beyond the scope of this article. We simply suggest that the plagioclase-melt system is one of the rare systems which fulfill these requirements.

But we have also shown that these requirements were not sufficient: for oscillatory behaviour to be more than an academic prediction, the damping coefficient k must be close to unity, and this in turn requires that the supersaturation be low enough. This explains why oscillatory zoning is common in phenocrysts of volcanic rocks and apparently absent or extremely rare in laboratory experiments<sup>29</sup>. Only when a magma body cools very slowly can plagioclase crystals come to an appreciable size in very low supersaturation conditions. Our quantitative model is certainly oversimplified. More laboratory experiments are needed to improve our understanding of plagioclase growth kinetics, especially in view of the variety and complexity of zoning patterns. That plagioclases are often more complicated than other minerals probably implies that they record a longer history, long residence times being allowed for even in quiescent magmas because of the low plagioclase-melt density contrast<sup>30</sup>.

Remarkably, when oscillatory zoning occurs the planar interface is extremely stable. This is attested by an observation made by Bollinger<sup>12</sup> on oceanic basalts: in these, small glass inclusions

are sometimes trapped by the growing crystal but do not lead to the formation of dendrites, showing that these lateral perturbations are stabilized (Fig. 6). Such a stability is expected for low supersaturations<sup>31,32</sup>. However, a few samples show contorted bands not conforming to prominent faces11. It would be interesting to investigate how the time delay in equation (4) affects the stability of the interface shape.

#### Conclusions

Our new theory explains the phenomenon of oscillatory zoning which is observed in many naturally grown plagioclase crystals. The theory is based on a simple model of the interface kinetics sensitivity to concentration changes in the melt. The mechanism suggested is probably very general but its effects can only be observed in specific conditions. We believe that an oscillatory zoned plagioclase is a pathological case of crystal growth which enables us to study a fundamental process, that is the response of the crystal growth rate to concentration changes. This process may be responsible for some other characteristics of crystal growth which remain poorly understood, such as the stability of a planar interface.

We thank Claire Bollinger for photographs and for many discussions on observations of plagioclase crystals.

## Glucocorticoids regulate expression of dihydrofolate reductase cDNA in mouse mammary tumour virus chimaeric plasmids

Frank Lee\*, Richard Mulligan\*\*, Paul Berg\* & Gordon Ringold\*

Departments of \* Pharmacology and ‡ Biochemistry, Stanford University School of Medicine, Stanford, California 94305, USA

Fusions between the mouse mammary tumour virus long terminal repeat and a mouse dihydrofolate reductase cDNA have been constructed in a SV40 vector. When these plasmids are transferred into recipient cells, the production of dihydrofolate reductase is regulated by glucocorticoid hormones. These results define a hormonally responsive region of the viral genome.

ALL steroid hormones seem to function largely via a common molecular mechanism in which the hormone first associates with a specific soluble receptor protein present in target tissues<sup>1,2</sup>. This interaction causes an alteration in the receptor that increases its affinity for binding sites in the cell nucleus<sup>3,4</sup>. The net effect of steroid action is to alter the pattern of proteins synthesized by the cell, probably by altering the transcription of a few specific genes<sup>5</sup>. It is widely documented that steroidreceptor complexes have DNA-binding properties<sup>2</sup> and that nuclear translocation reflects association of the complexes with

† Present address: Center for Cancer Research, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA.

DNA<sup>6</sup>. Furthermore, both genetic and biochemical evidence has suggested that DNA binding may be involved in eliciting a biological response<sup>7</sup>. To date, however, there is no direct evidence that interactions with DNA lead to changes in transcription or that steroid-receptor complexes must interact with particular DNA sequences to alter gene expression.

We have used mouse mammary tumour virus (MMTV)infected cells as a model to study the regulation of specific gene expression by steroid hormones<sup>8</sup>. When integrated into host cell DNA, the viral genome (the provirus) is transcribed by cellular RNA polymerase II<sup>9</sup> and production of viral RNA is stimulated by glucocorticoid hormones such as dexamethasone 10. Several

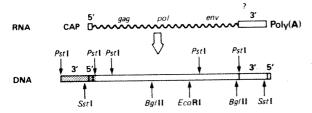

Fig. 1 The structure of the RNA and DNA forms of the MMTV genome. The RNA (~9 kilobase [kb]) form is shown with the putative coding regions indicated: gag, group-specific antigens, core proteins; pol, viral reverse transcriptase; env, viral envelope glycoprotein; ?, a postulated but unidentified gene product<sup>14</sup>. The linear form of MMTV proviral DNA is shown below; on integrating into cell DNA, this structure (with minor modifications at the ends) is maintained. At each end is a LTR consisting of sequences coding for both the 5' and 3' ends of viral RNA; these are shown as the boxes with the structure 3' (~1,200 bp)/5' (130 bp). The PsII fragment from the left-hand end (shown stippled) contains all but a few base pairs of one LTR in addition to 135 bp coding for RNA beyond the 5' leader or 'strong-stop' sequence. This PsII fragment was used as the MMTV fragment in construction of the plasmids shown in Fig. 2.

lines of evidence suggest that hormonal stimulation of MMTV RNA synthesis is mediated by the same intracellular glucocorticoid receptors that are involved in regulation of cellular genes<sup>11</sup>. Like other retroviruses, MMTV DNA integrates at many sites, perhaps even randomly, in the host genome<sup>12</sup>. Studies of viral RNA production in many different clones of MMTV-infected cells suggest that hormonal regulation of MMTV gene expression is not site specific; indeed, there are multiple cellular sites where the provirus is under hormonal control<sup>12</sup>. This argues against the hypothesis that regulation of viral gene expression occurs as a result of integration into a hormonally regulated site on the host chromosome.

In the present studies we sought to determine whether MMTV encodes its own promoter as well as a region required for glucocorticoid responsiveness. Our approach is based on one used successfully in the study of bacterial gene regulation, entailing the construction of a gene fusion between the regulatory region from the gene of interest and the coding region of a second gene whose activity can be conveniently assayed and whose function can be selected for *in vivo*. The expression of the fused gene may then be subject to the control signals present on the regulatory region.

As with other retroviruses, MMTV proviral DNA is bounded by two identical regions composed of sequences derived from both the 5' and 3' ends of the viral genome. These regions are called long terminal repeats (LTRs) and in MMTV are ~1,200 base pairs (bp) long (Fig. 1). The location of the 5' end of MMTV RNA corresponds to a site represented by the junction of the 3' and 5' sequence in the left LTR (Fig. 1), suggesting that the promoter for viral transcription lies within this 1,200-bp region. We have constructed fusions between the MMTV LTR and a cDNA containing the coding region for mouse dihydrofolate reductase (DHFR); the expression of this enzyme can be selected for in the appropriate host cell. These fusions were constructed in a plasmid DNA vector which allows expression of inserted genes after these molecules are introduced into recipient cells<sup>13</sup>. Analyses of the expression and hormonal regulation of these recombinant molecules have allowed us to identify the LTR of MMTV as a region which confers glucocorticoid responsiveness.

## Construction of MMTV-dhfr recombinant plasmids

The PstI fragment from the left end of the viral DNA encompasses an entire LTR (except for 5-10 bp at the extreme left-hand end). The cap site on the 5' end of MMTV RNA is located ~270 bp from the right-hand end of the PstI fragment (ref. 14 and J. Majors and H. Varmus, personal communication); transcription proceeds in the right-hand direction (Fig. 1). It therefore seemed probable that both the promoter for viral RNA synthesis and the sequences involved in hormonal regulation are located within this fragment. We therefore converted the ends of

this 1,450-bp fragment (see Fig. 2 legend) by addition of *HindIII* 'linkers' to facilitate its insertion into the unique *HindIII* site of the vector pSV2dhfr (Fig. 2a). This is a hybrid vector composed of sequences from the papovavirus SV40, the *Escherichia coli* plasmid pBR322 and cDNA coding for the mouse DHFR<sup>15</sup>. Sequences derived from pBR322 allow cloning and propagation of the plasmid in *E. coli* while those derived from SV40 contain processing signals allowing production of a functional messenger RNA for DHFR within mammalian cells<sup>16</sup>.

Individual colonies harbouring the resulting plasmid were screened to identify molecules containing the MMTV fragment oriented in the same direction as the DHFR-coding region. Such a configuration of the MMTV-dhfr fusion would allow transcription initiating at a promoter within the viral fragment also to transcribe dhfr. This plasmid, designated pSVMdhfr, is shown in Fig. 2b. In addition, a derivative of pSVMdhfr, constructed by deleting the SV40 fragment which contains the early promoter (Fig. 2c) and called pMTVdhfr, retains the putative MMTV promoter and regulatory region.

## Transformation characteristics of dhfr-containing plasmids

Dihydrofolate reductase catalyses the formation of tetrahydrofolate, a cofactor essential for many one-carbon transfer reactions such as in the biosynthesis of glycine and thymidine. A cell line<sup>17</sup> derived from Chinese hamster ovary (CHO) cells provides an ideal recipient for the *dhfr* vectors in DNA transformation experiments. These cells are defective in DHFR and, unlike wild-type cells, are unable to grow in medium lacking glycine,

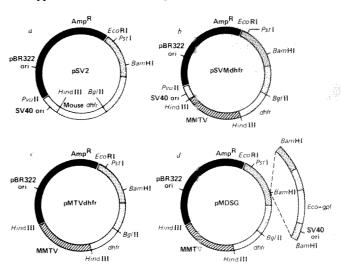

Fig. 2 Structure of plasmid vectors containing mouse dhfr and E. coli gpt. The solid black segment of each plasmid is a 2.3-kb fragment of pBR322 extending from the EcoRI site to the PvuII size which contains the lactamase gene (ampicillin resistance) and the origin of replication. The lightly stippled region of pSV2, pSVM and pMDSG between the PvuII and HindIII sites is a 325-bp fragment of SV40 (coordinates 0.65-0.71) containing the early promoter and the SV40 origin of replication. The other stippled regions are SV40 sequences encoding the intron for small T antigen (lightly stippled, SV40 coordinates 0.44–0.56) and the site for polyadenylation for early mRNA (heavily stippled, SV40 coordinates 0–0.19). All are described in ref. 13. The hatched region on pMTV, pSVM and pMDSG is the MMTV LTR. The open regions are either mouse dhfr cDNA15 or E. coli gpt13. Transcription from both the SV40 early promoter and the MMTV promoter is in the anticlockwise orientation, as are the coding sequences of dhfr and gpt. The sizes of the fragments are drawn only approximately to scale. Derivatives of pSV2dhfr were constructed as follows: The 1.4-kb PsrI MMTV LTR fragment was treated with T4 DNA polymerase to remove protruding ends, then HindIII linker fragments were added by ligation with T4 ligase. This fragment was inserted at the unique HindIII site of pSV2dhfr separating the SV40 origin fragment from dhfr sequences to produce pSVMdhfr pMTVdhfr (c) was generated by digesting pSV2dhfr with Pvull and HindIII. adding HindIII linkers to the Poull site and inserting the modified MMTV fragment. Colonies were screened to isolate molecules containing the MMTV DNA in the appropriate orientation pMDSG (d) was constructed by inserting a 2.2-kb BamHI fragment containing the SV40 origin/promoter fragment fused to Eco-gpt and SV40 RNA processing signals into the unique BamHI site of pMTVdhfr. This 2.2-kb fragment was derived by addition of a BamHI linker to the PvuII sitesof pSV2gpt13

Table 1 Transformation efficiencies and hormonal regulation of dhfr-containing plasmids in dhfr CHO cells

Vector	Structure	Transformation frequency	Hormonal regulation		
pSV2dhfr	SV40-dhfr	$1-2 \times 10^{-4}$	-	(0/4)	
pSVMdhfr	SV40-MTV-dhfr	$1 \times 10^{-4}$	+	(5/5)	
pMTVdhfr	MTV-dhfr	$1 \times 10^{-6}$	+	(3/3)	
pMDSG	MTV-dhfr: SV40-gpt	$1 \times 10^{-4}$	+	(3/3)	
pSVMdhfr'	SV40-VTM-dhfr	$1-2\times10^{-5}$	***	(0/4)	
pSV0dhfr	dhfr	$\leq 1 \times 10^{-7}$	Not de	termined	

Transformations were performed using the calcium phosphate co-precipitation method of Graham and van der Eb $^{18}$ . In brief,  $10-15~\mu g$  of circular plasmid DNA were precipitated with CaPO $_4$  and added to  $10^6$  cells growing in non-selective medium (Ham's F12 medium). Four hours after addition of DNA, cells were relycerol shocked' with 20% glycerol in phosphate-buffered saline (PBS) according to the method of Frost and Williams $^{25}$ . Medium was replenished the following day and the cells allowed to grow for 2 more days in non-selective conditions. Cells were then passaged into selective medium (Dulbecco's minimal essential medium  $+34.5~\mu g$  ml $^{-1}$  proline);  $10^6$  cells were plated per 10-cm dish. Medium was changed every 2-3 days and dhfr $^*$  clones became visible 7–10 days later. Transformation frequencies are reported as transformants per cell (for example, 100 colonies on a dish plated with  $10^6$  cells yields a frequency of  $10^{-4}$  transformants per cell). Hormonal regulation was determined either by methotrexate resistance (Fig. 3) or  $^3 H$ -methotrexate binding (Table 2); the numbers in parentheses indicate the number of individual transformants analysed and the proportion which were hormonally responsive. In pSVMdhfr', VTM indicates that the MMTV fragment was inserted in the anti-sense orientation.

thymidine and hypoxanthine. One can identify clones expressing the *dhfr* gene present on the transforming DNA by selecting for clones able to grow in the absence of one or more of the required supplements.

DNA was introduced into the CHO dhfr cells using the transformation procedure of Graham and van der Eb<sup>18</sup>. A calcium phosphate precipitate containing 15  $\mu$ g of plasmid DNA was added to 10<sup>6</sup> cells growing in non-selective medium; after transfer into selective medium, colonies were seen within 7–10 days. When pSV2dhfr DNA was used we observed 100–200 colonies (frequency  $\sim 1-2\times 10^{-4}$  per cell). Similar results have been obtained by Subramani et al. 6. The expression of dhfr in these cells is apparently directed by the SV40 early promoter because very few transformants (frequency  $\leq 1\times 10^{-7}$  per cell) are observed if transformations are attempted with a plasmid (pSV0dhfr) lacking the SV40 promoter/origin fragment (Table 1). PSV0dhfr was generated by deleting the region between the *PvuII* and *HindIII* sites of pSV2dhfr (Fig. 2a).

Similar experiments were performed with pSVMdhfr and pMTVdhfr. As shown in Table 1, the frequency of transformation with pSVMdhfr is similar to that with pSV2dhfr. The possibility exists, however, that the SV40 early promoter, located directly upstream of the MMTV LTR, is responsible for dhfr expression by readthrough transcription. This could occur with or without removal of MMTV sequences via a posttranscriptional splicing event. Results obtained with the pMTVdhfr vector eliminate this possibility because the SV40 promoter is absent. When CHO dhfr cells were infected with this DNA, transformants were indeed obtained, although at a considerably reduced frequency ( $\sim 10^{-6}$  per cell; Table 1). Nevertheless, the ability to isolate dhfr+ colonies following transformation with pMTVdhfr suggests that sequences present on the MMTV LTR are serving a promoter-like function; this is supported by studies of the 5' end of the dhfr RNAs in the transformants (see below).

We considered whether pMTVdhfr is less efficient at producing dhfr<sup>+</sup> colonies because the MMTV promoter is intrinsically inefficient. Such a weak promoter might produce levels of dhfr RNA only marginally sufficient to support growth in selective medium, thereby leading to reduced numbers of transformants. Thus we constructed another vector derived from pMTVdhfr in which the MMTV-dhfr fusion could be introduced into cells without directly selecting for dhfr expression; DHFR production might be detectable in the CHOdhfr<sup>-</sup> cells even if those levels were not sufficient to support growth. This vector, designated pMDSG (Fig. 2d), contains a DNA fragment that encodes the E. coli xanthine-guanine phosphoribosyl transferase (gpt)

gene under SV40 early promoter control inserted at the BamHI site of pMTVdhfr. The expression of the E. coli gene can be selected for in the CHOdhfr cells using the dominant selection procedure described by Mulligan and Berg<sup>13</sup>. The frequency of gpt\* clones obtained with pMDSG approximates the frequency of dhfr<sup>+</sup> transformants obtained with pSV2dhfr or pSVMdhfr  $(1 \times 10^{-4} \text{ per cell})$ . Three individual clones were picked, grown to mass culture and transferred to DHFR-selective medium. Surprisingly, all three clones grew as well as other dhfr transformants (data not shown). Furthermore, when pMDSG was used to transform cells selecting for dhfr directly, transformants also arose at a frequency of  $\sim 1 \times 10^{-4}$  per cell (Table 1). The relatively high level of transformation with pSVMdhfr and pMDSG, compared with that with pMTVdhfr, seems to be due to the presence of the SV40 fragment encompassing the promoter and origin of replication (S. Subramani and P. B. M. Fromm and P.B., F.L. and G.R., unpublished observations). This novel effect of the SV40 promoter/origin region on the efficiency of DNA mediated transformation will be described in greater detail elsewhere.

#### Expression and glucocorticoid regulation of dhfr in transformants

Regardless of differences in transformation frequencies, our results suggest that the dhfr cDNA can be expressed when fused to the MMTV LTR. This would be consistent with the presence of a promoter on this fragment of MMTV DNA, perhaps near the cap site. Our major interest in these experiments was to ascertain whether the expression of dhfr in these MTV-dhfr fusions could be regulated by glucocorticoids. A positive answer would suggest that the viral DNA indeed carries its own regulatory site.

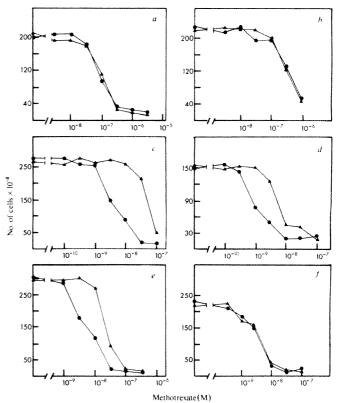

Fig. 3 Methotrexate inhibition of CHOdhfr cells transformed with dhfr cDNA-containing plasmids. Individual clones of CHOdhfr cells arising from transformation with the indicated plasmids were grown in selective medium (Dulbecco's minimal essential medium + 39.5 µg ml<sup>-1</sup> proline). In each case, ~10<sup>5</sup> cells were plated on 6-cm dishes either in the presence or absence of 10<sup>-6</sup> M dexamethasone. Twenty-four hours later, methotrexate was added to individual dishes at the indicated concentrations. Fresh medium containing methotrexate was added after 2 days and the surviving cells counted after 2 more days. a, Wild-type CHOKI cells; b, transformant pSV2dhfr.1; c, transformant pMTVdhfr.2; d, transformant pMDSG.8; e, transformant pSVMdhfr.4; f, transformant pSVMdhfr'.6. Dexamethasone absent (•) or present (•).

Table 2	<sup>3</sup> H-methotrexate binding of cell extracts					
	c.p.m. <sup>3</sup> H-metho					
Transformant	-Dex	+Dex	Fold induction			
pSV2dhfr.1	9.882	8,745	0			
pMTVdhfr.1	116	571	5			
pMTVdhfr.2	444	1.148	3			
pMTVdhfr.3	972	5,111	5			

Cells of individual clones were grown in Dulbecco's minimal essential medium + proline in the presence or absence of  $10^{-6}$  M dexamethasone (Dex) for 2 days. Cells were removed from dishes with PBS/EDTA and washed once with PBS.  $1-2\times10^7$  cells were resuspended in 1 ml of 0.05 M potassium phosphate buffer pH 7.4. The suspended cells were frozen and thawed three times in a dry ice/ethanol bath, and then centrifuged for 15 min in a microfuge.  $^3$ H-methotrexate (Amersham, 200 mCi mmol $^{-1}$ ) was added to equal amounts of extract from each cell line ( $\sim300~\mu$ g total protein in 50  $\mu$ l) and allowed to bind in the dark for 10 min at 25 °C. The mixture was passed over an 8-ml Sephadex G-50 column equilibrated in 0.01 M KPQ4 pH 6, 0.15 M KCl. The counts in the excluded volume were determined by counting in a scintillation spectrometer. In subsequent experiments we observed four- to fivefold inductions in all three pMTVdhfr clones.

Initially we attempted to measure DHFR in pMTVdhfr transformants using a standard enzymatic assay which measures conversion of <sup>3</sup>H-folate to <sup>3</sup>H-dihydrofolate and tetrahydrofolate. However, the levels of the enzyme are too low to be detected reproducibly in these cells using such an assay (F.L. and G.R., unpublished results). We therefore used methotrexate, a folate analogue which inhibits DHFR and thus inhibits cell growth, to estimate levels of the enzyme. Cells were plated in various concentrations of methotrexate, in either the presence or absence of dexamethasone, and the number of cells on each dish determined 4-5 days later. Figure 3a shows the results of such an experiment using wild-type CHO-Kl cells. The concentration of methotrexate required to inhibit growth of these cells by 50% is  $\sim 10^{-7}$  M; dexamethasone has no effect on the cells' sensitivity to methotrexate. Similar results are observed when pSV2dhfr transformants of the CHOdhfr cells are examined (Fig. 3b). Again, methotrexate sensitivity is unaffected by hormone treatment; this is true of four independent pSV2dhfr transformants we have examined.

In contrast, in experiments using pMTVdhfr transformants, the cells were considerably more resistant to methotrexate in the presence of dexamethasone than in its absence (Fig. 3c); the hormone-treated cells are resistant to  $\sim 10-20$ -fold more methotrexate. Furthermore, the levels of methotrexate required to inhibit growth of these cells  $(10^{-9}-10^{-8} \, \mathrm{M})$  is lower than that required to inhibit pSV2dhfr transformants. We believe this indicates that the MMTV promoter is less efficient than either the SV40 early or the cellular dhfr promoter.

In cells transformed with pMDSG DNA, dexamethasone also increases the resistance to methotrexate (Fig. 3d). Similar results have been obtained with several clones of pSVMdhfr transformants (Fig. 3e). Indeed, all cells transformed with a plasmid containing dhfr cDNA fused to the MMTV LTR in the proper orientation exhibit an approximate 10-fold increase in methotrexate resistance when grown in the presence of dexamethasone. If, however, we use a vector in which the MMTV LTR is inserted into pSV2dhfr in the opposite orientation relative to the dhfr cDNA (pSVMdhfr'), resultant transformants do not respond to dexamethasone (Fig. 3f). We do not know whether the dhfr expressed in these cells arises from a promoter on the opposite strand of the MMTV LTR. Nevertheless, the results of all the experiments indicate that the MMTV LTR is required for hormonal regulation of dhfr and that it must be in the proper orientation (Table 1).

Previous studies<sup>19</sup> have indicated the lack of a 1:1 correlation between the amount of DHFR present in a cell and a cell's sensitivity to methotrexate. To obtain a more quantitative estimate of the levels of DHFR in the transformed cells, we have measured <sup>3</sup>H-methotrexate binding to DHFR in cell extracts. Table 2 summarizes the results of such an experiment. pMTVdhfr-transformed cells clearly contain three- to fivefold more DHFR when grown in the presence of dexamethasone than in its absence; as described above, this results in a 10-20-fold increase in methotrexate resistance. Cells transformed with

pSV2dhfr contain higher levels of DHFR; however, these levels are unaffected by the hormonal status of the cell. Similar experiments with extracts from pMDSG- and pSVMdhfr transformants indicate that glucocorticoids result in a consistent three- to fivefold increase in levels of DHFR. All the data are in agreement with the methotrexate growth-inhibition studies.

Note that the level of induction of DHFR in the CHO cells is somewhat lower than the average 10-fold induction of MMTV RNA in mouse mammary tumour cells and much lower than the 50-500-fold level of induction of MMTV RNA in infected HTC, rat hepatoma cells. The reasons for these differences are obscure, although we have observed that the concentration of glucocorticoid receptors in the CHO cells is  $\sim 5-10\%$  that of HTC cells. We are investigating whether the induction of dhfr or other gene fusions can be augmented in cells with higher levels of receptor. Indeed, recent experiments in mouse 3T6 cells using pSVM plasmids containing the Eco-gpt gene rather than dhfr cDNA, indicate that production of xanthine-guanine phos-

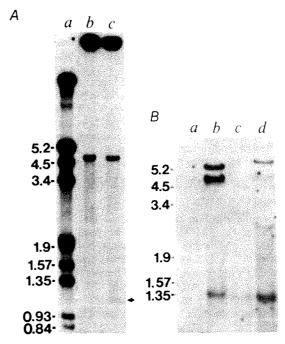

Fig. 4 A, S<sub>1</sub> nuclease mapping of MTV-dhfr RNA made in transformant pMTVdhfr.2. The <sup>32</sup>P-end-labelled probe for the hybridization was prepared as follows. pMTVdhfr plasmid was cut at the unique Bg/II site at the end of the dhfr cDNA (see Fig. 2). After treatment with alkaline phosphatase and labelling the 5' ends with <sup>32</sup>P-ATP and T4 polynucleotide kinase, the linear DNA was digested with EcoRI. The two resulting fragments were run on an agarose gel and the 4.5-kb EcoRI-BglII fragment containing the MMTV LTR and dhfr cDNA labelled at the Bg/II end was isolated from agarose. Total cytoplasmic RNA was isolated from pMTVdhfr.2 cells grown with or without dexamethasone  $(10^{-6})$  as described previously26. Poly(A)-containing RNA was isolated by binding to oligo(dT) cellulose. Approximately 5  $\mu g$  of poly(A)-containing RNA was hybridized with an excess of end-labelled DNA fragment in 80% formamide according to the method of Berk and Sharp<sup>20</sup>. Hybridization was performed at 50°C for ~16 h. Hybrids were treated with S<sub>1</sub> nuclease (Boehringer-Mannheim) and run on a 1.4% agarose gel which was autoradiographed for 7 days. a,  $^{32}$ P-end-labelled  $\lambda$  DNA (digested with EroRI and HindIII; sizes are indicated in kb); b, MTVdhfr.2 RNA minus dexamethasone; c, MTVdhfr.2 RNA plus dexamethasone. The arrow indicates the ~1-kb RNA-DNA hybrid. The band in b and c at -4.5 kb is the reannealed EcoRI-Bg/II probe. The dark band at the top of b and c represents material that did not enter the gel. B, Analysis of pMTVdhfr DNA in three dhfr\* clones. Three independent dhfr<sup>+</sup> clones arising following transformation with pMTVdhfr DNA were picked and grown to mass cultures. Total cell DNA was prepared from each clone as well as from the parental CHOdhfr cells. 10 µg of each DNA was digested to completion with HindIII and run on a 0.8% agarose gel, and then transferred to nitrocellulose by the method of Southern<sup>22</sup> The filter was hybridized with  $-5 \times 10^6$  c.p.m. of  $^{32}$ P-nicktranslated pMTVdhfr DNA, washed and autoradiographed as described previously<sup>12</sup>. Order of samples: a, CHOdhfr; b, MTVdhfr.1; c, MTVdhfr.2; d, MTVdhfr.3. The molecular weight markers were unlabelled fragments of DNA cut with EcoRI and HindIII, visualized by ethidium bromide staining. The common band appearing in all the MTV dhfrclones, ~1.4 kb long, is the MMTV LTR fragment which is excised by HindIII (see Fig. 2)

phoribosyl transferase is augmented at least 10-20-fold by dexamethasone (F.L. and G.R., unpublished results).

## Moving the 5' end(s) of MMTV-dhfr RNA

To determine whether the RNA expressed in the pMTVdhfr transformants initiates within MMTV DNA, we analysed the 5' end of the transcripts by the procedure of Berk and Sharp<sup>20</sup>. The Bg/II-EcoRI fragment encompassing the MMTV-dhfr sequences of pMTVdhfr was labelled with <sup>32</sup>P at the Bg/II site. Hybrids between this fragment and poly(A)+ RNA from the cytoplasm of pMTVdhfr.2 cells were treated with S<sub>1</sub> nuclease and analysed by electrophoresis in 1.4% agarose gels. The hybrid band detected by autoradiography is ~1,000 bp long (Fig. 4a), indicating that the predominant 5' end of dhfr RNA maps to a site within the MMTV LTR, 250-275 bases upstream of the dhfr insert. Furthermore, the production of this RNA is stimulated in cells treated with dexamethasone.

The S<sub>1</sub> nuclease analysis shown in Fig. 4a contains a heterogeneous background of apparent hybrids 1.0-4.5 kbp long. These seem to be artefacts of incomplete S<sub>1</sub> digestion rather than random sites of initiation; the long exposure time required to see the hybrid band has made it technically difficult to overcome this problem. However, transformants grown in progressively increasing concentrations of methotrexate amplify the MMTV-dhfr fusion and overproduce the dhfr RNA several hundredfold21. S1 nuclease analysis of RNA from such cells indicates that >90% of the dhfr RNA molecules initiate at the same site within the MMTV LTR as that shown by the 1kilobase band in Fig.  $4a^{21}$ . In these conditions the background is eliminated because much shorter exposure times (4 h compared with 7 days) are required to visualize the authentic hybrid.

### Integration of pMTVdhfr DNA in transformants

To determine the fate of the plasmid DNA used for transformation of the CHOdhfr cells, we have analysed cellular DNAs from pMTVdhfr transformants by the procedure of Southern<sup>22</sup>. Cell DNAs were cleaved with HindIII, which cleaves pMTVdhfr twice, and the fragments resolved by agarose gel electrophoresis. After transfer of the DNA onto nitrocellulose filters, the plasmid sequences were detected by hybridization with pMTVdhfr DNA labelled with 32P by nick-

translation. As seen in Fig. 4b, the three independently isolated transformants harbour plasmid-related sequences in different locations within cell DNA, as judged by the different mobilities of the hybridizing bands. This is corroborated by analysis of DNAs digested with EcoRI (data not shown).

We have not yet mapped the sites of integration either within the host or the plasmid DNAs. Interestingly, in this limited sample of clones there seem to be only one to two copies of integrated vector DNA in the transformants. We have no evidence of free plasmid DNA being maintained within the pMTVdhfr-transformed CHO cells.

#### **Conclusions**

The results of the experiments described here provide evidence that the MMTV LTR contains sequences which are sufficient for glucocorticoid regulation of gene expression. This extends the observations of others that the entire MMTV genome is glucocorticoid sensitive when introduced into mouse L cells by DNAmediated transformation<sup>23,24</sup>. Whether glucocorticoids are acting by regulating transcription per se remains to be established. The LTR fragment we have used contains ~270 bp which encode the 5' end of MMTV RNA, and differences in RNA processing within this region may account for hormonal regulation of MMTV RNA production in virus-infected cells or of dhfr in the transformants described here. In addition, there may be other viral sequences outside the LTR or cellular sequences which contribute to the hormonal response. Whatever the mechanism(s), we are now in a position to determine which sequences within this MMTV fragment are required for hormonal responsiveness. It will be of interest to determine whether these sequences serve as specific recognition sites for the glucocorticoid-receptor complex.

We thank John Majors and Harold Varmus for providing a clone of the MMTV Pst fragment, Gail Urlaub and Larry Chasin for the dhfr-deficient CHO cells, and Barbara Dieckmann for help with the methotrexate growth-inhibition studies. This work was supported by USPHS grants GM25821, GM13235 and CA15513-04, and aided by a Basil O'Connor Starter Research Grant from the National Foundation-March of Dimes. F.L. was supported by a fellowship from the California division of the American Cancer Society. R.C.M. was a NSF predoctoral fellow.

## Hexose transport in hybrids between malignant and normal cells

M. K. White, M. E. Bramwell & H. Harris

Sir William Dunn School of Pathology, University of Oxford, South Parks Road, Oxford OX1 3RE, UK

The kinetic parameters of hexose uptake were measured in matched pairs of hybrids between malignant and normal cells. Each pair consisted of a hybrid in which malignancy was initially suppressed and a segregant tumour derived from it. Comparisons were also made between tumour cells and non-tumorigenic derivatives selected from the tumour cell populations in vitro. Without exception, malignancy, as defined by the ability of the cell to grow progressively in vivo, was found to be linked to a systematic decrease in the Michaelis constant of the hexose transport system.

© 1981 Macmillan Journals Ltd

FOLLOWING the initial observation of Hatanaka et al.<sup>1</sup>, many authors have reported that morphological transformation of fibroblastic cells in vitro by certain oncogenic viruses is associated with an increase in the uptake of glucose by the cell. Although conflicting reports exist, the majority view is that the increase in uptake is due to an increase in the  $V_{\rm max}$  for glucose transport. Occasional reports of a reduction in the  $K_{\rm m}$  of the glucose uptake<sup>2,3</sup> have been difficult to reproduce<sup>4,5</sup>. There has been little work, however, and no formal kinetic study, on the relationship between glucose uptake and tumorigenicity.

Recent observations made in this laboratory have rekindled our interest in this problem. Bramwell and Harris<sup>6</sup> have shown that malignancy in hybrid cells is systematically linked to a structural alteration in the carbohydrate moiety of one particular membrane glycoprotein. Subsequent experiments provided strong circumstantial evidence that this protein had some role in glucose transport<sup>7,8</sup>. Gingrich et al.<sup>9</sup> have shown that a monoclonal antibody raised against partially purified preparations of the protein described by Bramwell and Harris delineates an antigen that behaves in a range of physiological tests as if it were the glucose transport protein. It was therefore of interest to see whether the structural change described by Bramwell and Harris was associated with any systematic functional alteration in hexose transport. Our approach has again been to compare hybrid cells in which malignancy is initially suppressed with malignant segregants derived from these hybrids. Isogeneic matched pairs of this kind provide a sensitive screen for markers linked to malignancy 10-14. We have also examined some non-malignant variants derived from tumour cells by selection for resistance to the lectin wheat-germ agglutinin°.

#### Hexose transport measurement

Hexose transport was measured by the uptake of 2-deoxy[ $^3$ H]glucose (1–70 mCi mmol $^{-1}$ , Amersham) in the following conditions. The cells were inoculated into 16-mm diameter tissue culture wells 24 h before assay. Each well received 2 ml of Eagle's minimum essential medium supplemented with 5% fetal calf serum and 5% newborn calf serum in which the cells were suspended at a concentration of 5– $15 \times 10^4$  per ml. The adherent monolayers were washed twice in phosphate-buffered saline PBS and 500  $\mu$ l of the radioactive sugar in PBS were added at 20 °C. Samples were collected at appropriate times by dissolving the cell monolayer, after two washes in PBS, in 440  $\mu$ l of 0.4 M NaOH. The extract was neutralized with 10  $\mu$ l of glacial acetic acid, mixed with 10 ml of Unisolve 1 and counted in a Packard scintillation counter.

The rate of uptake was derived from a six-point time course and was measured at four to six concentrations of 2-deoxyglucose in the range 0.1-5 mM. The uptake was linear for at least 10 min. Nonspecific uptake of the radiolabel was estimated by measuring the retention of L-[3H]glucose in parallel conditions, added at a concentration of 0.1 mM at the same specific activity per ml as the 2-deoxy[3H]glucose. The mean of the measurements obtained on each of six wells was subtracted from the 2-deoxy[3H]glucose uptake measurements, and the mean number of cells per well estimated by counting the trypsinized contents of six wells in a Coulter counter. For cells in suspension, uptake of the labelled 2-deoxyglucose was measured in 1.5-ml microfuge tubes. The cells were first pelleted by centrifugation for 4 s in a Beckman microfuge, washed once with PBS and then resuspended with the radioactive sugar. Cells were collected by centrifugation followed rapidly by a wash with ice-cold PBS. Allowance was again made for nonspecific retention of the radiolabel.

At each substrate concentration,  $S_i$ , an estimate of the reaction velocity,  $V_i$ , and the variance of that estimate were calculated by linear regression through the origin of the linear portion of the plot of 2-deoxyglucose uptake against time. The  $K_m$  and  $V_{max}$  values and their standard errors were calculated by a weighted linear regression of S/V against V, essentially as described by Cornish-Bowden<sup>15</sup>. The final weight applied to

each  $S_i/V_i$  was  $[V_i^2/V_{ar}V_i][V_{max}^2/(K_m+S_i)^2]$ . Inspection of the residuals in V confirmed that these weightings were acceptable  $^{16}$ .

For some cell lines uptake of D-glucose was measured by the silicone oil filtration centrifugation technique of Werdan et al.<sup>17</sup>. The kinetic constants thus obtained agreed well with those obtained by the uptake of 2-deoxyglucose as described above.

## Kinetic parameters of hexose uptake in parental malignant and normal cells

Table 1 gives the  $K_m$  and  $V_{max}$  values for the parental tumour cells and the diploid cells with which they were fused. The  $V_{
m max}$ values are highly variable, as expected, for it is known that in some cells the  $V_{\text{max}}$  of the hexose uptake is very sensitive to cell density and other conditions of culture. The  $V_{\rm max}$  values for some of the tumour cells are substantially lower than those for the diploid fibroblasts. There is clearly no correlation between tumorigenicity and a high  $V_{\rm max}$  in vitro. On the other hand, the tumour cells and the diploid cells differ consistently in the  $K_{\rm m}$ , the  $K_m$  values for the tumour cells being about half those for the diploid cells. The variation in  $K_m$  in the different fibroblast populations probably represents genotypic variation, as the duplicate values were derived from measurements on cells freshly isolated from two different animals. The PG19 tumour is derived from a C57BL mouse and is syngeneic with the C57BL fibroblasts

The question of whether the reduced  $K_m$  seen in the tumour cells is fortuitous or whether it is closely linked to the genesis of the malignant state can now be explored by comparing the matched pairs of hybrids, as we have described.

### Lymphoma × fibroblast crosses

The origin and characteristics of clone 1G, a hybrid clone derived from the lymphoma×fibroblast cross (YACIR×CBAT6T6 fibroblast), have been described previously<sup>18</sup>. The clone initially produced no tumours even with inocula of  $4\times10^6$  cells per mouse (sublethally irradiated, syngeneic, newborn animals), but after several weeks' cultivation in vitro, a malignant subpopulation was generated that overgrew the cultures. Early passages of clone 1G were recloned and the secondary

lymphocytes	Suspension culture		1.740 ± 0.085	$4.5 \pm 0.17$

PG19 is an HGPRT<sup>-</sup> derivative of a melanoma that arose spontaneously in a C57BL mouse. YACIR is a Moloney virus-induced lymphoma; an HGPRT<sup>-</sup> derivative was used. A9HT is a malignant derivative of the A9 cell line selected by passage through the animal. SEWA is a polyoma virus-induced osteosarcoma. TA3HaB is an HGPRT<sup>-</sup> derivative of the TA3 Hauschka cell line (details of these tumours are given in refs 10, 19). The fibroblasts were secondary cultures derived from trypsinized mouse embryos and were assayed at early passages as shown. The lymphocytes were teased from adult mouse spleen and purified by centrifugation in Ficoll-Paque.

clones tested for tumorigenicity. Two of these secondary clones, 1G1 and 1G8, were selected for further study. 1G8 produced no tumours with inocula of  $5\times10^5$  cells per mouse while 1G1 produced tumours in about 90% of the animals with this inoculum.

Three tumours derived from 1G1 were explanted and the cell populations assayed in vitro (clone 1G1T1, T2, T3). The kinetic constants for clone 1G8 are shown in Table 2. Clone 1G1 gave markedly nonlinear reciprocal plots, but the plots for the tumours derived from 1G1 were linear and their kinetic constants are also shown in Table 2. It is clear that the  $K_m$  for hexose transport of the three 1G1 tumours is substantially lower than that of the non-malignant clone 1G8 (a factor of almost 3).

It seemed reasonable to assume that the curvilinearity of the reciprocal plots for clone 1G1 was due to a mixture of cells in the population assayed. Clone 1G1 was therefore recloned to give tertiary clones 1G1A, E, F, H and J. Clone 1G1A still gave a curvilinear plot, but clones E, F, H and J gave linear plots with the  $K_{\rm m}$  and  $V_{\rm max}$  values shown in Table 2. Each of these clones gave the low  $K_{\rm m}$  characteristic of tumorigenic cells. These results thus support the view that tumorigenic variants are generated in the initially non-malignant cell populations and progressively overgrow the cultures. As no tumours were produced by direct injection of clone 1G8, we attempted to select from this clone subclones capable of growth in agarose, in the hope that such subclones might be enriched for cells capable of progressive growth in vivo. From three dishes, each seeded with 10<sup>5</sup> cells in agarose as described by Steinberg and Pollack<sup>19</sup>, five primary colonies were obtained, of which three survived isolation and further subculture (clones 1G8a, b, c). These gave 80-100% take incidences at  $5 \times 10^5$  cells per mouse. Table 2 shows the  $K_{\rm m}$ and  $V_{
m max}$  values for these clones and for tumours derived from them (1G8bT1 and T2). Both the clones themselves and the tumours produced by them have  $K_m$  values two to three times

Table 3 Kinetic constants of hexose uptake in melanoma × fibroblast hybrids and in a lectin-resistant melanoma derivative

lower than that of the non-tumorigenic clone 1G8 from which they were derived.

The association between reduced  $K_{\rm m}$  for hexose transport and tumorigenicity is thus not fortuitous. Malignant derivatives obtained directly by the inoculation of the hybrid cell population into the animal or indirectly by selection in semi-solid medium systematically show a reduction in  $K_{\rm m}$  compared with the non-tumorigenic hybrids from which they were derived.

#### Melanoma × fibroblast crosses

Crosses between the PG19 melanoma derivative and diploid fibroblasts homozygous for the T13H translocation produced only 4 tumours out of a total of 167 mice given inocula of  $2-3\times10^6$  cells per animal<sup>18</sup>. The kinetic constants for two clonal populations of this cross, clones 7 and 8, and a tumour produced from clone 8 (clone 8T1) are shown in Table 3. The hybrids in which malignancy is suppressed show high  $K_m$  values (more than three times the value for the parental PG19 tumour cells); the tumour produced by clone 8 shows a marked reduction in  $K_m$  compared with that of clone 8 itself.

## A melanoma derivative selected for resistance to wheat-germ agglutinin

Bramwell and Harris<sup>6</sup> found that selection of PG19 cells for their ability to grow in lethal concentrations of wheat-germ agglutinin produced derivatives with greatly reduced tumorigenicity. One such line (C) produced no tumours in 17 animals with inocula of  $5 \times 10^4$  cells per animal. This line was recloned and one of the secondary clones, PG19WGAR clone C2, was assayed. This non-tumorigenic clone had a high  $K_m$  comparable with that of the PG19×T13HT13H fibroblast hybrids in which malignancy was suppressed (Table 3). Changes in tumorigenicity produced by wheat-germ agglutinin selection are thus also associated with changes in the  $K_m$  for hexose transport.

### Fibrosarcoma × lymphocyte crosses

Crosses between diploid lymphocytes and the malignant L-cell derivative A9HT show suppression of malignancy  $^{20}$ . Assay of two highly suppressed clones, clones 3 and 4, showed their  $K_{\rm m}$  values to be  $2.240\pm0.160$  and  $2.080\pm0.120$  (Table 4), compared with  $1.170\pm0.079$  for the parental tumour cell (Table 1). A tumour derived from another such clone (A9HT  $\times$  C57BL lymphocyte clone 2T1) resembled the parental tumour cell in having a  $K_{\rm m}$  value of  $1.123\pm0.046$ .

## Fibrosarcoma derivatives selected for resistance to wheat-germ agglutinin

Selection of A9HT cells for resistance to wheat-germ agglutinin produced some derivatives that had lost tumorigenicity and others that retained it<sup>21</sup>. Clones A9HTWC and A9HTWD were both resistant to 25  $\mu g$  ml $^{-1}$  wheat-germ agglutinin, but whereas clone WC failed to produce any tumours with inocula up to  $6.6\times10^6$  cells per animal, clone WD remained as tumorigenic as the original A9HT parent cell. Table 4 shows that the  $K_{\rm m}$  for hexose transport of the non-tumorigenic clone is more than twice that of the tumorigenic clone.

Table 4 Kinetic constants of hexose uptake in fibrosarcoma×lymphocyte hybrids and in lectin-resistant fibrosarcoma derivatives

#### Polyoma virus-induced osteosarcoma × fibroblast crosses

As previously described, hybrids between SEWA and diploid cells are highly unstable<sup>18,22</sup>. Malignant segregants are generated in this cross at a very high frequency so that the tumorigenicity of the hybrid clones is variable. Hybrids that initially fail to produce tumours become tumorigenic again on continued cultivation in vitro. Early assay of a fresh set of nine hybrid clones isolated from a cross between SEWA and fibroblasts homozygous for the Rb7BnR translocation showed  $K_m$ values for these clones ranging from 0.8 to 2.9 mM; in some cases the reciprocal plots were initially curvilinear, as described for the YACIR×fibroblast crosses. The clones isolated were obviously a heterogeneous collection. Two clones, C1 and F, which initially gave high Km values, were grown continuously in vitro and their K values determined at intervals. The results (Table 5) show that on continued cultivation the  $K_{-}$  values fell progressively. Clone F, tested in vivo, initially produced no tumours, but soon became tumorigenic. The tumours produced from clones C1 and F gave lower  $K_m$  values than those of the

cells inoculated. There is clearly further selection for lower  $K_m$ in vivo.

#### Discussion

Our findings leave little doubt that malignancy, as defined by the ability of cells to grow progressively in vivo, is closely linked to a decrease in the  $K_m$  of the membrane hexose transport system. As the difference between malignant and non-malignant cells becomes more pronounced at lower external hexose concentrations, it is not difficult to see how the reduction in  $K_m$  might confer a selective advantage on malignant cells in vivo. The cell density in a primary tumour nodule is high and the blood supply precarious, so that the availability of hexose could easily be limiting. A decrease in the  $K_m$  of the hexose transport system might thus make the malignant cell a more effective scavenger of whatever hexose is available than the normal cells with which it must compete

Two general questions arise concerning the mechanism of the change in  $K_m$ . The first is whether it affects only the hexose transport system or whether other membrane transport systems behave similarly in malignant cells. The second question is whether the change in  $K_m$  reflects the operation of a structurally modified or different hexose transport system, or whether this change is produced as a secondary consequence of more generalized membrane changes. The answer to the latter question must wait until the elements of the hexose transport system have been unequivocally identified and subjected to formal structural analysis. In the light of our previous findings6, we are exploring the possibility that modification of the carbohydrate moiety of the hexose transport protein influences the  $K_m$  of the transport process.

We thank Mrs Ruth Hennion and Mr Stephen Greig for their help, and Dr S. J. Goss for his advice on the statistical aspects of the work. The work was supported by the Cancer Research Campaign, of which M.E.B. is the James Hanson Fellow. M.K.W. is a Scholar of the MRC.

## Innermost parts of accretion disks are thermally and secularly stable

#### Marek Artur Abramowicz

Department of Astrophysics, Oxford University, South Parks Road, Oxford OX1 3RQ, UK

There is strong evidence that various types of exotic astronomical objects (quasars, active galactic nuclei, Cyg X-1, SS433) can be explained by accretion disks orbiting black holes. Most of the proposed models of such objects are plagued by instabilities. It is widely held, for example, that all accretion disks must be thermally and secularly unstable in their innermost parts, which seems to be in direct conflict with observations. Much effort has been made to find a stabilizing mechanism operating in the innermost parts of the disks. Here I show that such a mechanism does exist. It is of general relativistic origin, is purely mechanical-operating independently of viscosity and other microphysical processes—and is similar to the mass loss caused by Roche lobe overflow in close binaries.

Permanent address, Nicolaus Conermons Center, Warsew, Poland,

It is generally believed that the inner regions of standard, thin accretion disks are both thermally and secularly (L-E) unstable. This is because the most important stability condition,

$$\left. \frac{\mathrm{d} \ln Q^{+}}{\mathrm{d} \ln H} \right|_{U} < \frac{\mathrm{d} \ln Q^{-}}{\mathrm{d} \ln H} \right|_{U} \tag{1}$$

is not satisfied by any one of the possible relevant cooling mechanisms  $(Q^{-})$  when the dissipation, the rate of heat generation  $(Q^+)$ , is determined by the standard viscosity law. In equation (1), H denotes the height of the disk and U the surface density.

Piran<sup>1</sup> gives the most general discussion of the stability problems in terms of four quantities k, l, m, n

$$k = \frac{\mathrm{d} \ln Q^{-}}{\mathrm{d} \ln H} \Big|_{U}, \qquad l = \frac{\mathrm{d} \ln Q^{-}}{\mathrm{d} \ln U} \Big|_{H} \tag{2}$$

$$m = \frac{\mathrm{d} \ln \nu}{\mathrm{d} \ln H} \Big|_{U}, \qquad n = \frac{\mathrm{d} \ln \nu}{\mathrm{d} \ln U} \Big|_{H} \tag{3}$$

which describe phenomenologically a wide range of different viscosity laws and cooling mechanisms, in particular all those discussed in the accretion disk context. In equation (3), the quantity  $\nu$  is the kinematic viscosity. The standard viscosity

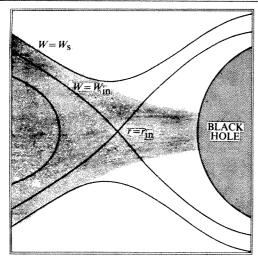

Fig. 1 Equipotential surfaces close to the inner edge of the disk.

law has m = 2, n = 0. Non-standard viscosity laws have m < 2,

A recently discovered<sup>2</sup> mass loss mechanism which operates close to the inner edges of accretion disks orbiting black holes removes both thermal and secular instabilities. There are no instabilities even in the extreme case when the ratio of radiation pressure to the total pressure,  $\beta = 1$ , and when the Shakura-Sunyaev  $\alpha$ -viscosity parameter,  $\alpha = 1$ . The conclusion holds for both standard and non-standard viscosity laws.

Piran's arguments and his stability conditions are used here. After concluding that there is no combination of any known cooling mechanism with the standard viscosity law which gives rise to a stable inner disk region (radiation pressure and electron scattering-dominated), Piran remarks that a secondary wind escaping from the disk surface would have a stabilizing effect. He admits, however, that generally this wind would be too small to change the main conclusion significantly. Nevertheless, he gives explicit forms of the necessary and sufficient stability conditions for thermal and secular stability of a disk with a secondary wind. The conditions are general and valid not only for winds, but for any mass loss from the surface. The mass loss is expressed by

$$\dot{M} \sim U^s H^r \tag{4}$$

and the stability conditions yield

$$(8s-3r)+(51s-9r)\beta-(3s+12r)\beta^2-X^2(m-k)>0$$
 (5a)

$$r(n+1-l)-s(m-k)>0$$
 (5b)

$$[2m+8(n+1)]+[9m+51(n+1)]\beta-3[m+n+1]\beta^2>0$$
 (5c)

$$[sm - (n+1)r] - Y^{2}[ml - (n+1)k] > 0$$
 (5d)

The explicit form of  $X^2$  and  $Y^2$  is not relevant here.

General relativistic effects in the gravitational field of a black hole cause a characteristic behaviour of the equipotential surfaces close to the inner edge of an accretion disk: one of the equipotentials,  $W = W_{\rm in}$ , crosses itself on the edge (see Fig. 1). If the surface of the disk,  $W \approx W_{\rm s}$ , slightly overflows the critical equipotential  $W = W_{in}$ , then mechanical equilibrium is slightly destroyed, causing mass loss. The physical picture is analogous to the case of Roche lobe overflow in close binaries.

Abramowicz, Calvani and Nobili<sup>3</sup> give expressions for the mass loss rate and efficiency of the cooling mechanism connected with the mass loss assuming only mechanical, not thermal, equilibrium. Their equations (5.19) and (5.13) valid close to the inner edge of the disk, that is for  $r \approx r_{\rm in}$ , read

$$\dot{M} \sim UH$$
 (6)

$$O^- \sim UH^3 \tag{7}$$

Thus, for this particular mass loss mechanism s = 1, r = 1, l = 1and k = 3 (for  $r \approx r_{in}$ ).

This result, when combined with the general stability criteria of equation (5), proves that accretion disks orbiting black holes are thermally and secularly stable close to their inner edges. This is true for both standard and non-standard viscosity laws and it does not depend on any particular value of  $\alpha$  or  $\beta$ .

Note that the stabilizing mechanism is purely general relativistic in its origin. This may be the only known situation when a general relativistic effect stabilizes a configuration, especially a rotating one.

The physics beyond this formal proof is simple: consider a small, purely thermal (that is with U = constant) perturbation which produces an excess heat  $(Q^+ > Q^-)$ . If the excess heat cannot be removed from the disk, the disk expands. This causes increased Roche lobe overflow: the location of the Roche lobe depends only on the angular momentum at  $r = r_{in}$  and does not change during the expansion. Because the cooling increases very strongly with the increasing overflow and the heating does not, the disk reaches the state  $Q^- = Q^+$  and achieves thermal stability.

More detailed treatment of this phenomenon will be published elsewhere where I shall discuss the radial size of the region,  $r_{\rm in} \le r \le r_*$ , affected by this stabilizing mechanism. The size, of course, depends strongly on the particular situation. A rough estimate gives  $r_* > H(r_{in}) f(r_*) \approx \text{few } r_{in}$ , where f =(thermal time scale/free-fall time scale). For the supermassiveblack-hole case this is enough to stabilize the whole inner (radiation pressure- and electron scattering-dominated) region of the disk.

I thank Geoffrey Bath and Tsvi Piran for helpful discussions.

### Milliarcsecond structure of BL Lac during outburst

#### R. L. Mutel\*, H. D. Aller† & R. B. Phillips‡

The well known object BL Lacerate is the prototype of a class of compact extragalactic sources which display rapid flux and polarization changes at radio and optical wavelengths and a nearly featureless optical spectrum<sup>1</sup>. After a period of relative quiescence, BL Lac has recently undergone a violent outburst at radio wavelengths, accompanied by rapid changes in degree of polarization and position angle (Fig. 1)<sup>2,3</sup>. For a better understanding of the physical mechanism responsible for the variable emission, we have mapped the radio structure at 5 and 10.6 GHz at three epochs during the large flux outburst of 1980 with an intercontinental VLBI array using telescopes in Bonn, West West Germany: Green Bank, Virginia; Westford. Massachusetts; Fort Davis, Texas; and Owens Valley, California. The synthesized beam had a resolution of about 1.0 m arc s at  $\lambda$  6 cm and 0.5 m arc s at  $\lambda$  2.8 cm, corresponding to linear sizes of 5.9 and 2.9 lyr (light year) at the source (using a redshift of 0.0695 and a Hubble constant of 55 km s<sup>-1</sup> Mpc<sup>-1</sup>). We show here that comparison of the size and flux density of the core component with the flux history provides evidence for relativistic beaming effects, independent of detailed model considerations. The flux densities shown in Fig. 1 were obtained at the University of Michigan radio observatory.

The observations were made at three epochs: 1980.41  $(\lambda 6 \text{ cm})$ , 1980.73  $(\lambda 6 \text{ cm})$  and 1980.93  $(\lambda 2.8 \text{ cm})$ . During each epoch, one telescope had a technical failure so that only four telescopes were used in each mapping analysis. The telescopes used the MKII VLBI recording scheme<sup>5</sup> and were equipped

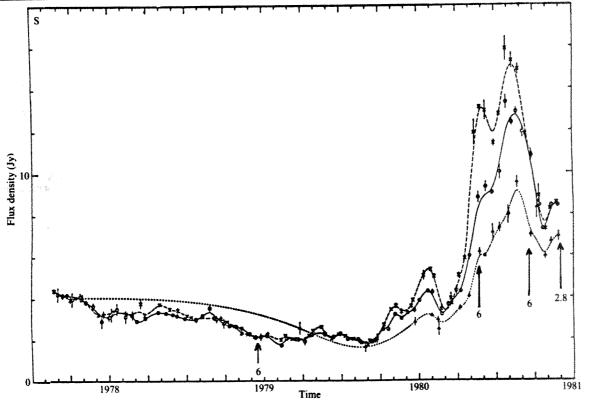

Fig. 1 Flux density compared with time at 4.8 GHz ( $\triangle \cdots \triangle \cdots$ ), 8.0 GHz ( $\longrightarrow$ ) and 14.5 GHz ( $\times -- \times --$ ). Data points are 2-week averages. Epochs of VLBI observations are shown by arrows where the number indicates wavelength of each observations.

with maser time standards. All observations were made using left circular polarization and a receiving bandwidth of 2 MHz. The data were correlated using the Caltech/JPL VLBI correlator. The mapping was done at the University of Iowa using a hybrid algorithm utilizing closure phase. For all three epochs, the resulting fits to the data were very good, and the maps are thought to be reliable to the 5% contour level. An example of the visibility data and corresponding hybrid model fit is given in Fig. 2 for the 1980.93 data at  $\lambda$  2.8-cm wavelength.

The  $\lambda$  2.8-cm hybrid map is shown in Fig. 3a, while the two  $\lambda$ 6-cm maps are shown in Fig. 4a, b. In each case, the restoring beam has been chosen by fitting an elliptical gaussian to the main beam of the array power pattern, which is obtained by Fourier transforming the transfer function for each observation. A remarkable aspect of the structure at all three epochs which is not apparent on the hybrid maps is the extreme narrowness of the source. For both  $\lambda$  6-cm observations, the source was completely unresolved when the baselines were aligned approximately east-west. The  $\lambda 2.8$ -cm data also show this effect, although there is some east-west resolution on the transatlantic baselines. This dominant north-south structure has been seen with more limited VLBI measurements<sup>7-9</sup> as early as 1971 and apparently indicates that there is an alignment mechanism in the central source which is stable compared with the time scale of individual flux outbursts.

To clarify the detailed north-south structure, we have shown one-dimensional profiles of brightness temperature along a position angle of  $0^{\circ}$  for each map. Figure 2b shows the  $\lambda$  2.8-cm profile, while Fig. 5 shows the  $\lambda$ 6-cm profiles at both epochs. In addition, we have shown the north-south brightness profile for the three-component gaussian model of Pearson and Readhead based on data taken at  $\lambda$ 6-cm in 1978 December when BL Lac was dormant (see Fig. 1). To compare brightness temperatures in a uniform way, we have used the same restoring beam for all three  $\lambda$ 6-cm profiles. This beam is too small for the December 1978 model (because only US baselines were used) so that the detailed structure of the components is probably unreliable. We have also convolved our data with the same restoring beam of Pearson and Readhead and find no evidence

of the southerly component extending  $\sim 10 \text{ m arcs s } (60 \text{ lyr})$  seen in their 1978 map.

Comparison of the  $\lambda$  2.8 map (Fig. 3) with the flux history data of Fig. 1 shows that the source is much larger than would be expected from simple light travel time arguments. The current outburst can be dated from ~1979.8 when the total flux density is  $\sim 2$  Jy at  $\lambda$  6 cm and  $\lambda$  2.8 cm. Without relativistic effects, the maximum source size in ~1980.9 would be 1.1 lyr, whereas the north-south extent of the  $\lambda$  2.8-cm map is  $\sim 4.5$  lyr. This discrepancy could be understood in several ways: (1) simultaneous, independent brightening of causally unconnected regions; (2) activation by a single 'trigger' mechanism located approximately midway between two distant emitters; or (3) relativistic beaming effects causing a time 'speed-up' in the observed flux changes. Explanation (1) seems very improbable, particularly considering the 3-yr dormant period which preceded the outburst, while explanation (2) requires a highly specialized geometry.

The relativistic beam model<sup>11</sup> has been widely used to explain the properties of compact radio sources<sup>12-14</sup>. The model consists of a central object with two opposed particle beams moving with relativistic bulk velocities. If the line of sight to the observer is nearly parallel to the beam axis, he will see the forward beam Doppler-boosted in intensity. The true angular source size is the apparent size as observed in the VLBI data, but the flux variations are observed 'speeded up' by the Lorentz factor, which in the present case is  $\gamma \sim 4$ .

A further argument supporting relativistic beaming in this source is the anomalously high brightness temperatures implied by the flux density variations. In the absence of relativistic effects, the inferred brightness temperature of the core component would be at least  $10^{13}$  K based on the light travel size. This violates the inverse Compton limit of  $T_{\rm B} \leq 10^{12}$  K for an opaque synchrotron emitter. On the other hand, the observed brightness temperatures (based on the actual measured angular sizes) are  $T_{\rm B} \leq 3 \times 10^{11}$  K for all three observations.

The  $\lambda$  6-cm maps do not have sufficient angular resolution to show the details of the evolution of the jet during the outburst. However, comparison of the 1980.41 and 1980.73 brightness

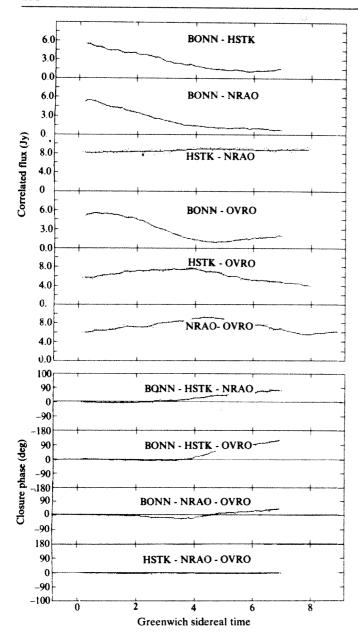

Fig. 2 Four-min averages of fringe amplitude and closure phase for the 1980.93 data at 10.6 GHz. Also shown is the fit from the hybrid map shown in Fig. 3a.

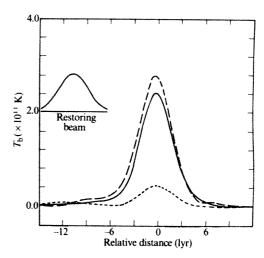

Fig. 5 One dimensional profiles of peak brightness temperature along position angle 0° for 5 GHz maps at three epochs. Dotted line is epoch 1978.93, solid line is epoch 1980.41 and dashed line is epoch 1980.73. Note that the relative position between epochs can not be determined from the VLBI data and is not necessarily as shown here. Also the same restoring beam has been used for all three epochs. This over-resolves the 1978.93 data (see text).

profiles (Fig. 5) show that there has been a small, but definite increase in the core size, of  $\sim 0.5$  lyr. This is actually a lower limit, as the true size has been convolved with a restoring beam whose dimensions are comparable with the core size. In addition, all three profiles show a weak, extended southerly component. The detailed nature of this component is uncertain because of the limited dynamic range of the maps. However, we have found differences in the closure phase on identical baseline triangles in the comparison of 1980.41 and 1980.72 data which we are confident are caused by changes in the extended southerly structure. The extended structure is not seen on the  $\lambda$ 2.8-cm profile, indicating that perhaps the extended emission has become optically thin between  $\lambda$  6 and  $\lambda$  2.8 cm.

We thank the staffs of the five observatories for assistance with the observations. The work was supported in part by NSF grants AST-79-10128 and AST-78-24192.

# Diffuse interstellar absorption bands between 2.9 and 4.0 µm

#### D. A. Allen

Anglo-Australian Observatory, Epping, New South Wales, Australia

#### D. T. Wickramasinghe

Royal Observatory, Blackford Hill, Edinburgh EH9 3HJ, UK

IRS7, the obscured M supergiant near the galactic centre, is an excellent source against which to study interstellar absorption bands near 3- $\mu$ m wavelength. Previously we considered the 3.4- $\mu$ m absorption band as evidence that interstellar grains include an organic component. We report here superior data between 2.9 and 4.0  $\mu$ m, and find a broad absorption trough with numerous discrete features stretching from 2.9 to 3.6  $\mu$ m. Although no definite identification of the material producing this absorption is possible, there is some indication that complex organic molecules may be involved.

Because of the strong and variable telluric absorption features in the waveband of interest, we now describe our observing methods in some detail. We used the IR photometer-spectrometer at the f/15 focus of the 3.9-m Anglo-Australian Telescope. In this instrument a circular variable filter (CVF) is scanned rapidly and repeatedly across the image of a source; in this case each spectral scan between 2.9 and 4.0 µm required 5.8 s. The resolution of the CVF is  $\lambda/\Delta\lambda \sim 100$ . Scans were alternated in direction, and at the end of each pair of scans the telescope was driven back and forth between IRS7 and a patch of sky 80 arcs to the north. This procedure ensured that the data were not contaminated by signals from other sources in the galactic centre area appearing in the reference sky beam. A circular aperture of 3.5 arcs diameter was used to reject nearby sources, in particular the very cool object IRS3. The resulting spectrum shows a weaker contribution from cool dust at 4 µm than any previously published. Indeed, IRS7 may have no intrinsic excess radiation from circumstellar dust, and the contribution we see may be contamination from nearby sources.

Approximately every 5 min we made observations in exactly the same manner of the nearby K0 giant star  $\gamma$  Sgr. Five separate observations of IRS7 were individually bracketed by observations of  $\gamma$  Sgr. All observations were made when both objects lay within  $10^{\circ}$  of the zenith. The observations of  $\gamma$  Sgr monitored changes in the telluric absorption bands. The changes found on this occasion were quite small.

Figure 1 shows our raw data in the vicinity of the strongest telluric features, between 2.9 and 3.45  $\mu$ m. Figure 1b refers to the ratio IRS7/ $\gamma$  Sgr, and shows the five separate observations, displaced for clarity, and their mean: the major features repeat well from one spectrum to the next. Note the narrow absorptions near the channels 23 and 30. We present the raw spectra of  $\gamma$  Sgr, showing the telluric absorptions in Fig. 1a. These are displaced from the features in the quotient spectra, indicating that the latter do not arise from poor cancellation of the telluric features

An independent observation made in July 1980 enables a final check of these features. This observation was less favourable because IRS7 and  $\gamma$  Sgr lay at a greater zenith distance and a different CVF gave a resolution of only 50. Finally, the 1980 data used a larger aperture and smaller beam separation. Nonetheless, between 2.9 and 3.45  $\mu$ m the same spectral features were seen except for the first few data points at the short-wavelength end of the spectrum.

Also shown in Fig. 1a is the ratio of the spectrum of  $\gamma$  Sgr to a G dwarf star, whose spectrum is expected to be featureless in this spectral region. The telluric cancellation is not as good on this occasion because of the greater time gap between the two observations. This ratio indicates that the spectral features

observed in IRS7 are not introduced by the use of  $\gamma$  Sgr as a calibrator

Spectra obtained of the M supergiant VX Sgr confirm that it does not show any absorption features in the 2.9–4.0  $\mu$ m region. Thus all the absorption bands in the spectrum of IRS7 are of interstellar origin.

Figure 2 shows the resultant spectrum, including the portion from 2.0 to 2.5  $\mu m$ . The deep photospheric CO absorption of the M supergiant is clearly seen in this spectral region, and as expected there is no indication of the 1.9 or 2.7  $\mu m$  steam absorption bands. Outside the CO band we expect IRS7 to show a black-body continuum. Note that there is roughly a 10% uncertainty in the relative heights of the 2 and 3  $\mu m$  spectra caused by the necessary use of a small aperture and the presence of seeing of 1–2 arc s. The broken line on Fig. 2 indicates where the 1980 spectrum digresses from the 1981 data.

To reveal the depth of the absorption we have constructed a continuum in Fig. 2 which we have forced to fit through the 2.0-2.25 and 3.6-3.95 µm sections of the data. Three parameters describe such a continuum: the black-body temperature of the star, assumed to be 3,200 K, the extinction at a chosen wavelength (2.2 µm: 2.5, derived from ref. 1), and the form of the reddening law. For the latter we use  $A_{\lambda} \propto \lambda^{-n}$ , where  $A_{\lambda}$  is the reddening in stellar magnitudes at wavelength  $\lambda$ . We assumed n = 2 based on ref. 3. With any reasonable adjustment of these parameters we cannot fit the designated continuum points. To do so we add a cool black-body component representing emission from dust. This may arise in IRS7 itself, in the nearby IRS3, or in fainter, unmapped sources. Two more parameters are then involved: the dust temperature and the intensity of the dust emission. The continuum plotted in Fig. 2 has a dust component of 550 K having 0.19 of the star's flux at

Relative to this continuum we find a complex of absorption

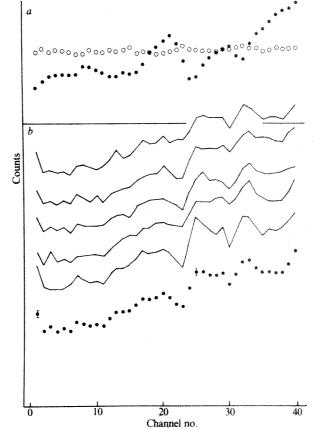

Fig. 1 b, IRS7 divided by the standard  $\gamma$  Sgr plotted against channel number in the region of the telluric bands  $(2.9-3.45 \,\mu\text{m})$ . The solid curves are based on five individual sets of observations obtained as described in the text.  $\bullet$ , The mean spectrum a, The raw spectrum of  $\gamma$  Sgr showing the telluric bands  $(\bullet)$  and the ratio of  $\gamma$  Sgr (K0) to that of a G dwarf star  $(\bigcirc)$ .

bands stretching from 2.9 to 3.6 µm. Two dominant bands lie at 3.03 and 3.40  $\mu$ m, and have optical depths of 0.41 and 0.32 respectively. The increased optical depth of the 3.4 µm feature relative to our previous result1 reflects the improved definition of the continuum. This optical depth would be further increased if the redness between 3.6 and 3.95 µm were due to absorption rather than to the addition of cool dust.

Figure 2 shows all of the absorption features we believe to be real, and a few (marked?) which are less certain. The absorption clearly breaks up into many discrete features and two of these (at 3.192 and 3.295 µm) are quite narrow. Whilst the broad features centred at 3.03 µm and 3.40 µm presumably arise in solid grains, the narrow features may have a gaseous origin. We have found no convincing identification for either, although many hydrocarbons have stretching absorptions in this spectral range. However, laboratory data are not available for even quite simple, incompletely bonded molecules (for example CH<sub>3</sub>) such as might be found in the interstellar environment. Quite narrow absorption bands are found in the absorption spectra of some solids, such as methane<sup>4</sup> and methyl alcohol<sup>5</sup>.

Suitable data on the absorption properties of solid materials are not available, and laboratory work is needed to match the present spectra. We see no evidence for water ice in the available data. The absorption band at 3.03 µm is displaced from that of water (3.06 µm) and is narrower. If water ice is present, it contributes little to the absorption. Similarly, solid ammonia (2.91 µm) is not present. Molecules involving carbon and hydrogen, on the other hand, can produce absorption near both 3.0 and 3.4 µm, and are thus particularly attractive identifications. Organic molecules containing OH and NH bonds also cause absorption near 3.0 µm (refs 6, 7). The wavelengths of CH, NH and OH vibrations depend critically on the composition of the solid and only a few cases<sup>5</sup> of astronomical interest have been discussed in the literature. The H bonded solid complex of H<sub>2</sub>O, CH<sub>3</sub>OH and NH<sub>3</sub> (ref. 5) has a feature due to NH at 2.97 µm but there is no correspondence with the rest of the spectrum.

It has been suggested recently<sup>8</sup>, that surface functional groups attached to reactive sites on small carbon grains may be responsible for the IR features seen in IRS7. Although there are some interesting wavelength coincidences (aromatic -CH (3.3 \mum),  $CH_3$  (3.4, 3.5  $\mu$ m), -CHO (3.5, 3.65  $\mu$ m)) no information has been given on band strengths and shapes to enable a detailed comparison.

We have looked at published spectra of specific grain models involving organic polymers which could be possibilities for the organic component of interstellar grains. The polymer-like material in carbonaceous chondrites show absorption due to CH near 3.3  $\mu m$  and weak absorption at 3.0  $\mu m$ . Clearly this material will not produce a fit to the astronomical data even over a restricted wavelength region. However, hydrated silicates of

meteoritic origin show a broad absorption feature centred near 3 μm<sup>10</sup>. This may be relevant in view of the possible identifications of the 9.7 µm and 18 µm features in the galactic centre with silicates. We consider it significant that the yellow component of UV tholin<sup>2,9</sup> looks qualitatively similar to that of IRS7 in the 3.4-μm region. In particular the shoulder at 3.36 µm, the central component at 3.4 µm and the component at 3.48 µm are present in the laboratory data with wavelengths agreeing to within  $\pm 0.02 \,\mu m$ . This could indicate the existence of complex organic molecules in grains<sup>2,11,12</sup>. However, this material does not produce significant absorption near 3 µm as required by the IRS7 data. It is interesting that the satellite features at 3.36, 3.48 µm are also seen in the spectrum of polyformaldehyde suggesting that H<sub>2</sub>CO may be present as a structural unit13

We cannot rule out the possibility that a mix of simple organics might match the observed spectrum. This requires further investigation using laboratory data. However, as our data are of relevance mainly to the properties of dust in the diffuse interstellar medium it will be more appropriate to look at refractory materials related to the UV component of tholins such as the non-volatile residue produced in the laboratory experiments designed to simulate conditions in the interstellar medium described by Greenberg<sup>12</sup> and with predictions from the Hoyle-Wickramasinghe model<sup>11</sup>. The latter comparison has shown a remarkable similarity between the spectrum of IRS7 and that of dried bacteria (Escherichia coli) which will be reported elsewhere14

Finally emission features are found in this waveband in some H II regions and carbon-rich planetary nebulae (for example, NGC7027)15. These normally comprise a strong, narrow peak at  $3.29 \mu m$  and a weaker, broader feature peaking at  $3.40 \mu m$ . In this respect they mimic features in the relevant portion of the absorption spectrum of IRS7. However, the 3.03 and 3.192 μm features are not seen in emission in any objects. An interpretation of the absorption spectrum of IRS7 which simultaneously predicted the more restricted range of the emission bands would be very satisfying.

### Fractal dimensions of landscapes and other environmental data

#### P. A. Burrough

Department of Regional Soil Science, Agricultural University, Wageningen, The Netherlands

Mandelbrot has introduced the term 'fractal' specifically for temporal or spatial phenomena that are continuous but not differentiable, and that exhibit partial correlations over many scales. The term fractal strictly defined refers to a series in which the Hausdorf-Besicovitch dimension exceeds the topological dimension. A continuous series, such as a polynomial, is differentiable because it can be split up into an infinite number of absolutely smooth straight lines. A non-differentiable continuous series cannot be so resolved. Every attempt to split it up into smaller parts results in the resolution of still more structure or

<sup>\*</sup> Estimated from variogram. ‡ Estimated from block variance. † Estimated from power spectrum. § Estimated from covariance.

roughness. For a linear fractal function, the Hausdorf-Besicovitch dimension D may vary between 1 (completely differentiable) and 2 (so rough and irregular that it effectively takes up the whole of a two-dimensional topological space). For surfaces, the corresponding range for D lies between 2 (absolutely smooth) and 3 (infinitely crampled). Because the degree of roughness of spatial data is important when trying to make interpolations from point data such as by least-squares fitting or kriging<sup>2</sup>, it is worth examining them beforehand to see if the data contain evidence of variation over different scales, and how important these scales might be. Mandelbrot's work1 suggests that the fractal dimensions of coastlines and other linear natural phenomena are of the order of D = 1.2-1.3, implying that long range effects dominate. I show here that published data on many environmental variables suggest that not only are they fractals, but that they may have a wide range of fractal dimensions, including values that imply that interpolation mapping may not be appropriate in certain cases.

Berry and Lewis<sup>3</sup> have shown that the Weierstrass-Mandelbrot fractal function (WMF)

$$W(t) = \sum_{n=-\infty}^{\infty} \frac{\left[ (1-\mathrm{e}^{\mathrm{i}\gamma^n t}) \, \mathrm{e}^{\mathrm{i}\phi_n} \right]}{\gamma^{(2-D)n}}$$

 $(1 < D < 2, \gamma > 1, \phi_n = arbitrary phases)$ 

has a power spectrum  $P(\omega)$  that varies approximately as  $\omega^{-(5-2D)}$ , and a variance of increments  $V(t) = ([W(t_0) - W(t_0 + t)]^2)$  that varies as  $t^{A-2D}$  at the origin. If D > 1.5, V(t) is itself a fractal function. These results allow us to

estimate the fractional dimension D of a real series, either from the slope of the log-log plot of the power spectrum as  $t \to 0$ , or from

$$\frac{d \log V(t)}{d \log t} = 4 - 2D \qquad (t \to 0)$$

The variance of increments (or the half thereof, the semi-variance) is much used in geostatistical studies where, computed over distances, it is referred to as the variogram<sup>2</sup>. Computing the variogram is the first step in the interpolation procedure known as kriging which is used to assist estimation of mineral reserves, contouring groundwater surfaces, and so on. Thus many published data are available in this form and it is then a simple matter to calculate their dimensions D relative to the sampling interval used.

For a second-order stationary series, the variance of increments at a given lag is equal to twice the difference between the variance of the series and the covariance. Thus, D values may also be computed from covariances. In agriculture and soil science, many data have been published in the form of block variances; that is the variance within blocks of equal size plotted against block size. Because Yates showed that the variance for a block of a given size k is

$$s_k^2 = \frac{2}{k(k+1)} \sum_{h=1}^k (k-h+1) Vh$$

where  $s_k^2$  is the block variance of block length k, and Vh the variance increment for lag h, the slope of log Vh versus  $\log h(h \to 0)$  can also be estimated from these data.

Table 1 presents a selection of data so analysed, giving the study location, the type of environmental variable, the lag interval used for sampling and the estimated D value assuming that the real data are but a series of regularly spaced samples of a realization of the Weierstrass-Mandelbrot function over onedimensional space or time.

The data support Mandelbrot's assertion that D values of landscape and other data may range over many values. It is evident that most of the values reported here exceed 1.5, and many are greater than 1.8. Note that one of the smoothest surfaces imaginable in a landscape, a new airport runway, has a relatively high D, presumably because variations over long distance are low in amplitude. These data do not conform to a single roughness model as proposed by Sayles and Thomas,5 indeed, as Berry and Hannay<sup>6</sup> have commented, much wider ranges of roughness or randomness are to be expected.

These results should not be accepted uncritically, however. First, it is important to realize that the Weierstrass-Mandelbrot function is just one of a class of 'model' fractals. Its peculiarity is that it has a discrete and geometric spectrum, and this might make some of its properties non-universal among other fractals with the same D (M. V. Berry, personal communication).

Second, although some environmental data do appear to display the fractal property of statistical self-similarity at all scales, there are also many that show self-similarity over a limited range of scales, or over a few widely separated scales. For example, a variable with a highly regular spatial variability has a variogram that exhibits parabolic behaviour near the origin<sup>2</sup>. This is a good example where d log  $V(h)/d \log h$  becomes less steep as  $h \to 0$ , and it indicates that the ultra-short, short and middle range variations are trivial compared with the main variations seen at larger scales. In fact, computing D as  $h \to 0$  will in this case estimate D for the ultra-short range scales of variation.

Third, the form of the variogram is often highly dependent on sampling direction and sampling interval. It is well known that when a particular sample spacing tends to match the scale of a spatial pattern, the variance of increments can fall rapidly. Accordingly, when a sampling interval matches a particular scale of a phenomenon in the landscape it perceives an apparently lower D. If this is so, it would seem more appropriate to estimate D values from the parts of the variogram showing maximum slope. Table 1 also contains these data for those phenomena showing a maximum slope at positions other than

The results presented here suggest that Mandelbrot's D can be used as a useful indicator of the complexity of autocorrelations over many scales for natural phenomena. However, although many natural phenomena do display certain degrees of statistical self-similarity over many spatial scales, there are others that seem to be structured and have their levels of variability clustered at particular scales. This behaviour does not exclude them from the fractal concept. Mandelbrot<sup>1</sup> considers that it is quite acceptable to have a series of zones of distinct dimensions connected by transition zones. If this is reasonable, it means that the examination of D values would be useful for trying to separate scales of variation that might be the result of particular natural processes. Moreover, identifying such scales could be of enormous practical value because one could then tailor sampling to a particular scale range of the phenomenon in question, thereby improving the efficiency of expensive field investigations and the resulting interpolations. The high level of the D values for some soil and geological data reported here would seem to question the wisdom of interpolation mapping in certain instances, however, and it would seem worthwhile to use D values as a guide to how further mapping and interpolation should proceed.

Three Mile Island (TMI) and Peach Bottom (PB) reactors have introduced <sup>137</sup>Cs, <sup>134</sup>Cs, <sup>60</sup>Co, <sup>58</sup>Co and several other anthropogenic radionuclides into the lower Susquehanna River. Here we present the release history for these nuclides (Table 1) and radionuclide concentration data (Table 2) for sediment samples collected in the river and upper portions of the Chesapeake Bay (Fig. 1) within a few months after the 28 March 1979 loss-of-coolant-water problem at TMI. Although we found no evidence for nuclides characteristic of a ruptured fuel element, we did find nuclides characteristic of routine operations. Despite the TMI incident, more than 95% of the total 134Cs input to the Susquehanna has been a result of controlled low-level releases from the PB site. 134Cs activity released into the river is effectively trapped by sediments with the major zones of reactor-nuclide accumulation behind Conowingo Dam and in the upper portions of Chesapeake Bay. The reported distributions document the fate of reactor-released radionuclides and their extent of environmental contamination in the Susquehanna-Upper Chesapeake Bay System.

During the past 14 yr, five nuclear power reactors have operated for varying lengths of time at two sites on the Susquehanna River (Fig. 1). The first reactor, PB 1, was a 40-MW, gas-cooled reactor and operated from March 1966 to October 1974. Three others, PB units 2 and 3 (boiling-water reactors), and TMI unit 1 (a pressurized-water reactor), began power production in 1974 and each produces ~1,000 MW. TMI unit 2, a twin of TMI 1, was activated on 30 December 1978 but shut down on 28 March 1979 after the loss-of-coolant incident. As with the other nuclear power stations, minor amounts of <sup>137</sup>Cs, <sup>134</sup>Cs, <sup>60</sup>Co, <sup>58</sup>Co and other radionuclides are released with the coolant-water effluent. The radionuclide release history of these reactors has been compiled using Nuclear Regulatory Commission documents1 and is summarized in Table 1. The Peach Bottom plant has contributed most of the reactor-produced radionuclides introduced into the Susquehanna River, and from 1975 to 1979, the PB reactors have released >95% of the total <sup>134</sup>Cs input to the river.

In addition to reactor releases  $^{137}$ Cs (half life of  $\sim 30$  yr) has been introduced into the Susquehanna-Chesapeake Bay system as global fallout from atmospheric nuclear weapons testing. The major influx of fallout <sup>137</sup>Cs occurred between 1962 and 1964. Reil<sup>2</sup> used the distribution of fallout <sup>137</sup>Cs in Chesapeake Bay to study the hydrography of the estuary. Although other fission products and neutron activation nuclides, such as <sup>134</sup>Cs, <sup>66</sup> and 58Co are also produced during weapons tests, their short half lives ( $\sim$ 2, 5 and 0.2 yr, respectively) and low yields cause the

O, Core samples.

fallout contribution of these nuclides to be negligible. Consequently, observed <sup>134</sup>Cs, <sup>60</sup>Co and <sup>58</sup>Co activities in Susquehanna River sediments are a result of reactor releases only. Previous studies in the River Esk<sup>3,4</sup>, Hudson Estuary<sup>5-7</sup>, Columbia River Estuary<sup>8,9</sup>, James River Estuary<sup>10</sup> and Chesapeake Bay<sup>11-13</sup> have shown the usefulness of these particle-associated radionuclides as tracers for sediment transport and accumulation patterns and as tools for understanding river estuarine sedimentary processes.

Radionuclide activities were measured in surface sediment samples collected from the Susquehanna River and Upper Chesapeake Bay in May and September 1979. The sediment area sampled by each grab was  $\sim 15 \times 20$  cm and the sample depth  $\sim 10$  cm. The sediments were dried, ground with a mortar and pestle, and sealed in  $100\text{-cm}^3$  aluminium cans or  $550\text{-cm}^3$  Marinelli beakers depending on the sample size. The activities of  $^{137}\text{Cs}$ ,  $^{134}\text{Cs}$ ,  $^{60}\text{Co}$ ,  $^{58}\text{Co}$  and  $^{40}\text{K}$  (a naturally occurring radionuclide) were measured using a lithium-drifted germanium detector and multichannel analyser. The activity of naturally occurring  $^{40}\text{K}$  reflects the potassium content of the sediment (0.012% of the potassium in K-bearing minerals is  $^{40}\text{K}$ ) and correspondingly, quartz-rich sandy sediments or organic-rich peaty sediments are characterized by low  $^{40}\text{K}$  activities. Bomb- and reactor-produced  $^{137}\text{Cs}$  was detected in all surface

Bomb- and reactor-produced <sup>137</sup>Cs was detected in all surface sediment samples and activities ranged from 70 to 2,500 pCi kg<sup>-1</sup> (Table 2). The highest activities of reactor-produced <sup>58</sup>Co (a few hundred pCi kg<sup>-1</sup>) were detected in sediment samples near the TMI reactors. Although measurable activities (100–200 pCi kg<sup>-1</sup>) of reactor produced <sup>134</sup>Cs were also observed in the sediments near the TMI reactors (Table 2), the highest <sup>134</sup>Cs activities (400–1,680 pCi kg<sup>-1</sup>) were observed in the sediments near the PB reactors and just downstream behind Conowingo Dam (Fig. 2). We found no evidence in the river sediments for γ-emitting radionuclides which would

characterize a rupture of the fuel elements (such as  $^{95}Zr^{-95}Nb$ ,  $^{140}Ba^{-140}La$ ,  $^{141}Ce$ ,  $^{144}Ce^{-144}Pr$ ,  $^{108}Ru$  and  $^{106}Ru^{-106}Rh$ ). Table 2 shows that the gamma activities of reactor-released radionuclides in the sediments of the Susquehanna-Chesapeake Bay System are one to two others of magnitude less that that of naturally occurring  $^{40}K$  (Table 2). Concentrations of naturally occurring uranium and thorium decay-series radionuclides also greatly exceed the reactor products in our samples.

Vertical distributions of radiocæsium in our sediment cores are illustrated in Fig. 3. Cores \$H-2A, H-3 and C-4 were collected in May 1979 from behind the Safe Harbour, Holtwood and Conowingo Dams respectively (Fig. 1), and each was ~80 cm long. Box Cores 14 and 19 (each ~40 cm long) were collected in Upper Chesapeake Bay in August 1979. Gravity Core E was taken within the turbidity zone of Upper Chesapeake Bay (Fig. 1) in October 1976.

Although measurable activities of <sup>137</sup>Cs were observed throughout the entire lengths of cores H-3, C-4, E and 14, the activity of reactor-produced <sup>134</sup>Cs was generally confined within the top 10–15 cm (Fig. 3). The deepest appearance of <sup>137</sup>Cs in the sediment core indicates the beginning of significant fallout in

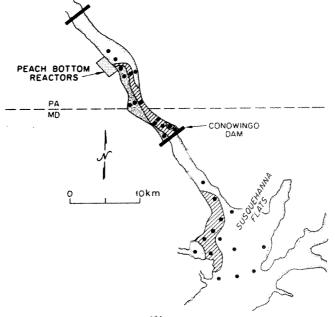

Fig. 2 Areal distribution of  $^{134}$ Cs activity in the surface sediments downstream of the Peach Bottom reactor site. All the samples, including those taken in sandy areas of Upper Chesapeake Bay, contained detectable activities of  $^{134}$ Cs (Table 2). The surface sediment  $^{134}$ Cs activities are kg $^{-1}$ :  $\boxtimes$ , >400 pCi kg $^{-1}$ ;  $\boxtimes$ , 150–400 pCi kg $^{-1}$ ;  $\square$ , <150-pCi kg $^{-1}$ .

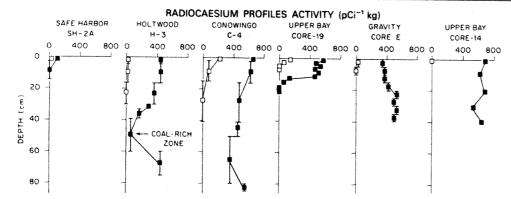

Fig. 3 Vertical distributions of radiocaesium in sediment cores indicate that the areas behind Holtwood and Conowingo Dams and areas within the turbidity zone of Upper Chesapeake Bay are sites of rapid sediment and radionuclide accumulation. Statistical counting errors are approximately the same size as the symbol (□, <sup>134</sup>Cs; ■, <sup>137</sup>Cs) illustrating the data point.

1954, and the deepest appearance of <sup>134</sup>Cs indicates the beginning of significant releases from the TMI and PB reactors. In addition, peaks in the radionuclide profiles may be correlated with the history of fallout or reactor releases to provide additional time-stratigraphical reference levels. Any rigorous attempt at obtaining sediment accumulation rates using these time-stratigraphical markers requires information concerning variations in sediment properties (such as grain size) and the extent of sediment mixing.

Our radiocaesium profiles (Fig. 3) indicate that the areas behind Holtwood and Conowingo Dams are presently zones of rapid sediment and radionuclide accumulation. Gross et al. concludes that one-half to two-thirds of the sediment load of the lower Susquehanna is trapped behind the three hydroelectric dams and that  $\sim 1 \times 10^6$  Mg of suspended sediment are annually discharged past Conowingo Dam during years without major floods. The low activities for reactor radionuclides and the lack of radiocaesium in the core collected behind Safe Harbour Dam indicate that either this reservoir has not been a major trap for fine particles and radionuclides during the past two decades or our samples are not representative of the area as a whole. A detailed budget of sediment accumulation behind the dams based on radionuclide data from these and several more recent cores, is in preparation (J.F.D and O.P.B.)

The sediment and radionuclides which escape from behind Conowingo Dam seem to be efficiently trapped along the western margin of the Susquehanna Flats (Fig. 2) or in the turbidity maximum area (Core E) of Upper Chesapeake Bay. Goldberg et al.13 have observed sediment accumulation rates as great as 8 cm yr<sup>-1</sup> (and <sup>239,240</sup>Pu activity distributions to sediment depths as great as 70 cm) in the turbidity zone area near the location of Gravity Core E. The elevated PCB concentrations (0.1 p.p.m.) at 35-40 cm (ref. 15) in Core E and our <sup>137</sup>Cs profile support the conclusions of Goldberg et al. 13 that during the past two decades this area has been a zone of rapid sediment and contaminant accumulation.

The depth of <sup>137</sup>Cs penetration in Core 14, collected near Baltimore (Fig. 1), indicates that this may also be an area of recent particle accumulation. The lack of <sup>134</sup>Cs activity in the surface sediments of this core indicates that Susquehannaderived particles at this site are markedly diluted by sediments from other sources.

As most of the <sup>134</sup>Cs activity was only recently released from the PB reactor site, and because much of this <sup>134</sup>Cs activity seems to be confined to near the sediment surface (Fig. 3), we can estimate the total <sup>134</sup>Cs burden in the sediments by integrating the 134Cs activities in our grab samples and using these values as representative of different areas in the river and upper bay. A detailed budget of 134Cs accumulation, based on more samples than those presented here, is in preparation but preliminary estimates indicate that almost all the 134Cs released into the Susquehanna River has been trapped within the sediments upstream of Baltimore<sup>16</sup>

Our distribution data indicate that: (1) reactor-produced radiocobalt and radiocaesium are sequestered by particles and deposited in low-energy environments; (2) levels of contamination, though measurable, are a small fraction of the total radioactivity resulting from naturally occurring radionuclides; and (3) these nuclides can provide valuable insights into the transport and accumulation patterns of particles and particleassociated pollutants introduced into the Susquehanna-Upper Chesapeake Bay system.

We thank E. Bondietti, B. Kimmel, T. Tamura and R. Turner for reviewing this manuscript. Most of the y spectrometric measurements were made at Lamont-Doherty Geological Observatory of Columbia University. We also thank A. Eaton,

## Field-capacity water extracts from serpentine soils

John Proctor, W. R. Johnston\*, D. A. Cottam\* & A. B. Wilson

Department of Biology, University of Stirling, Stirling FK9 4LA, UK

Soils derived from serpentinites and other ultramafic rocks have long been called 'serpentine soils' by biologists1. They often bear a distinctive vegetation with poor cover or rare species or both and have attracted botanical interest for centuries2.3. The chemical causes of the unusual vegetation have often been investigated using soil analyses of exchangeable and total quantities of ions or elements. These have shown that serpentine soils are rich in magnesium and have relatively high concentrations of nickel but low ones of calcium and other nutrients. Although these factors have been judged to be important in many serpentine soils, there have been few analyses of their soil solutions which would give a better assessment of likely soil toxicities and deficiencies. Moreover the soil solution can be effectively simulated in water-culture experiments to investigate directly the effect of each possible factor on plant growth. We report here (Table 1) the results of soil-solution analyses for a range of Scottish and Zimbabwean serpentine soils which bear unusual vegetation. These analyses have substantially altered previous conclusions concerning the chemical causes of serpentine vegetation7.

The soil solutions were extracted by centrifuging at 12,000g soil samples which had been maintained for up to 3 days at field capacity (moisture content after 24 h drainage). The solutions were analysed by standard atomic absorption techniques<sup>8</sup> for metals, the phenol disulphonic method8 (with modification in high chloride samples) for nitrate, the molybdenum blue method for phosphorus8 and by a silver titration method for chloride9. pH was measured using a glass electrode and bench pH meter.

The results are best discussed in the context of the three main chemical causes of plant growth on serpentines: high Mg/Ca quotient, high nickel and low nutrients.

The Meikle Kilrannoch soil is apparently uniquely toxic among British serpentines (J.P., unpublished results, and ref. 10) and there is evidence<sup>5,10-12</sup> to indicate that high magnesium is the prime cause of this toxicity. Magnesium toxicity depends on the concentration of calcium and, from soil exchangeablecation analyses it seemed that very low calcium exacerbates magnesium toxicity at Meikle Kilrannoch11. The soil-solution analyses (Table 1) offer a different explanation. The distinctive feature of the Meikle Kilrannoch soil solution is its high concentration of ions, particularly magnesium among the cations. Calcium is actually at higher concentrations than in other Scottish serpentines (in Table 1) but proportionally more calcium is required to ameliorate magnesium toxicity at higher solution concentrations of this element<sup>5,12,13</sup>

The soil-solution analyses have also been useful in judging the possibility that calcium deficiency may be an adverse factor in some serpentines. Several earlier workers had stressed the importance of calcium deficiency<sup>14,15</sup> but the demonstration of the very small absolute requirement for calcium by plants16 had suggested that calcium deficiency was unlikely to occur in serpentine soils. The lower soil-solution calcium concentrations at Coyles of Muick, Hill of Towanreef and particularly Green Hill (sites where soil exchangeable calcium is not very low<sup>17,18</sup>) still exceed the minimum calcium required by Zea mays 16. The possibility of calcium deficiency as a plant-determining factor in some serpentine soils should be reconsidered. Very low soil-solution calcium at Green Hill has been observed and three species of grass tolerant to this soil have root-surface

Samples collected moist in August 1980, stones > 1 cm diameter removed, wetted to field capacity a few days after collection and centrifuged after 1-3 days.

+ Chromium and cobalt analyses carried out on these samples: none exceeded the detection limit of 0.1 mg l

Samples collected from relatively dry soils in January 1977, sieved through a 2 mm mesh, air-dried, subsequent treatment as for Meikle Kilrannoch.

<sup>‡</sup> One sample was missing from the nitrate analyses. Three samples with nickel below the detection-limit (0.1 mg l<sup>-1</sup>) were not included in the calculation of mean and confidence limits for this element

<sup>§</sup> Samples collected moist in September 1976, sieved through a 2 mm mesh, air-dried, moistened to field capacity in laboratory in May 1977 and centrifuged after 3 days. ND, not determined.

hosphate species expressed as PO<sub>4</sub>

<sup>\*\*</sup> Nickel values were all below the detection limit (0.1 mg l<sup>-1</sup>) except for one sample from Green Hill with 0.18 mg l<sup>-1</sup> nickel.

phosphatases with activities unchanged in a range of calcium concentrations. Two grass species which grew poorly in Green Hill soil had calcium-sensitive root-surface acid phosphatases and it was inferred that the tolerant species were adapted to low soil calcium. In contrast, native Festuca rubra from Meikle Kilrannoch 19 has root-surface phosphatases with higher activities with increasing calcium, magnesium and nickel.

The use of water-culture experiments with Festuca rubra in media simulating soil solutions has shown that nickel is also likely to be toxic (at 0.7 mg l<sup>-1</sup> Ni<sup>2+</sup>), although less so than magnesium, at Meikle Kilrannoch<sup>13</sup>. Similar experiments with Agrostis stolonifera in simulated Keen of Hamar soil solutions have provided evidence of slight nickel toxicity (at 0.1- $0.2 \text{ mg l}^{-1} \text{ Ni}^{2+})^{20}$ . These experiments have allowed nickel toxicity in British serpentines to be assessed and helped to resolve conflicting evidence from soil and plant analyses and bioassays (J.P. unpublished data, and refs 10, 11, 18).

Earlier work in Zimbabwean serpentine soils had indicated the importance of nickel toxicity for plant growth<sup>21-23</sup>. Our soil-solution analyses support this conclusion, and show a low Mg/Ca quotient in the Zimbabwean samples, confirming that this factor is less important than a high nickel concentration.

The present results show that nutrient concentrations are not always low in serpentine soils. The nitrate concentrations at Meikle Kilrannoch are high and nitrate is the main balancing anion for magnesium at Coyles of Muick, Green Hill and Hill of Towanreef. Nitrate is lower at the Keen of Hamar. Here the site is close (all samples within 0.5 km) to the sea and the soil solutions resemble (with some enrichment of magnesium and nickel) ~1% seawater with Na<sup>+</sup> and Cl<sup>-</sup> as preponderant ions. Soil-solution phosphate concentrations in Table 1 are high but for this element the labile-pool size, for which we have no information, may be a more critical determinant of plant growth. Potassium concentrations range from low in the Scottish soils to moderately high in those from Zimbabwe.

Hydrogen and hydroxyl ions must contribute little to the total ion balance in these soil solutions as they are neutral to mildly acid. Table 1 shows direct measurements for four sites: measurements of soil pH (in a mix of equal proportions of soil and water) gave mean values of 6.7 for Meikle Kilrannoch, 6.1 for Kingston Hill and 6.2 for Tipperary Claims for samples collected close to those used for the soil-solution analyses.

The relevance of soil-solution extraction at field capacity can be questioned as soils are in this state for an unknown part of the growing season. Solution concentration can vary with the time of the year and with the method of extraction<sup>24,25</sup>. But cool moist conditions prevail at the Scottish sites and here the field-capacity extraction seems appropriate. Moreover, as the concentration of the soil solution increases on drying<sup>24</sup> the potentially toxic nickel in the field-capacity water extracts from the Zimbabwean samples represents a minimum level of nickel toxicity which must become much more acute. It is encouraging that F. rubra plants grown in water-culture media based on the field-capacity extracts from Meikle Kilrannoch soils have shown a broadly similar appearance, size and tissue element composition to the same species grown in the actual soils<sup>13</sup>.

Similar soil-solution analyses have been used successfully in recent studies of the vegetation of skeletal soils rich in copper, lead and zinc<sup>26,27</sup>. However, the interpretation of soil-solution analyses is less straightforward for soils with much organic matter where heavy metals are likely to be in complexes of unknown chemistry and toxicity19

## **Upper Cretaceous to Eocene pelagic** limestones of the Scaglia Rossa are not Miocene turbidites

#### Walter Alvarez

Department of Geology and Geophysics, University of California, Berkeley, California 94720, USA

#### William Lowrie

Institut für Geophysik, ETH-Hönggerberg, CH-8093 Zürich, Switzerland

The Scaglia Rossa is a pink limestone composed of 1-20% forams and  $\sim$ 5% clay in a coccolith matrix that outcrops extensively in the Umbria-Marches Apennines of northern peninsular Italy. It has universally been considered to be a pelagic sedimentary rock deposited during the late Cretaceous to middle Eocene. The Scaglia Rossa has been studied intensively as a record of micropalaeontological<sup>1-7</sup>, palaeomagnetic<sup>8-36</sup>, sedimentological<sup>31-34</sup>, and geochemical<sup>33,35-39</sup> events. Recently, Wezel<sup>40</sup> reported that the limestones are not of pelagic origin but are entirely turbiditic, and were deposited in the Miocene. He also criticized magnetic polarity stratigraphy investigations done on the Scaglia Rossa, concluding that the polarity is a function of sedimentation rate, not of geomagnetic field polarity. His evidence has cast doubt on previous stratigraphic information from the Scaglia Rossa<sup>41</sup> and compels us to respond. Although the observation by Coccioni<sup>42</sup> and Wezel<sup>40</sup> of the presence of fossils of anomalously young ages in clay seams between the limestone beds is of interest, we show here that the proposed redating of the Scaglia is wrong for several palaeontological, sedimentological and palaeomagnetic reasons.

Wezel stressed the importance of Coccioni's 42 first report of Miocene planktonic forams in clay partings between limestone beds in the Scaglia<sup>40</sup> but did not comment on Premoli Silva and Luterbacher's<sup>43</sup> conclusion that these volumes forems contaminants.

On checking these observations we have found that Miocene forams are indeed present in clay interbeds in various places. However, detailed examination of ~200 thin sections of Scaglia limestone beds from six localities, including 57 thin sections from the Bottaccione Gorge at Gubbio, spanning the same stratigraphic interval as Coccioni's 42 clay samples, did not reveal a single Miocene foram, although the spherical forms Orbulina and Praeorbulina, the most common types identified by Coccioni, yield distinctive circular sections. Wezel<sup>40</sup> found no detrital grains accompanying the younger forams, and because these forams are the same age as the turbiditic Marnosoarenacea Formation, which is rich in quartz and mica grains, he concluded that the Miocene forams could not be contaminants derived from the Marnoso-arenacea. However, in a test of this conclusion carried out at the University of California, A. Montanari (personal communication, 1981) washed clay from the Cretaceous-Tertiary boundary in the Bottaccione section at Gubbio and found rare quartz grains and particles of cemented quartz sandstone and siltstone, some of the latter actually containing Miocene planktonic forams cemented into the siltstone. He also found these materials by washing soil collected on the Scaglia Rossa outcrop face. These observations are striking proof that the Miocene forams are contaminants derived from the Marnoso-arenacea.

Wezel<sup>40</sup> illustrates one thin section from a hard limestone bed of the basal Palaeocene Globigerina eugubina zone showing a foram which he first identifies as the Upper Palaeocene to Middle Eocene planktonic form "Globorotalia ex gr. G. aragonensis - G. formosa" and later as "Globorotalia cf. aragonensis"; "ex gr." (out of group of) and "cf." (compare) indicate that the fossil could not be precisely identified. However, according to Premoli Silva (personal communication, 1980), the wall structure of this foram indicates that it is a benthic, not a planktonic type; it probably belongs to the genus Congotalites.

The Scaglia Variegata, Scaglia Cinerea and Bisciaro units, which overlie the Scaglia Rossa, have been found to contain an orderly sequence of Upper Eocene–Lower Miocene forams and coccoliths<sup>44–47</sup>. In Wezel's interpretation all previous work on these units must be wrong.

Wezel<sup>40</sup> considers that the Scaglia Rossa is a Cretaceous-Palaeocene sediment redeposited by turbidity currents during the Miocene. He therefore stresses the occurrence of turbiditic beds in some sections of the Scaglia Rossa. These beds, showing grading, sole marks and Bouma sequences, and described as 'detrital beds', 'calcarenites', or 'turbidites', are usually conspicuously white in a formation that otherwise is dominantly pink. Wezel<sup>40</sup> goes beyond other workers in considering other parts of the Scaglia Rossa to be of turbiditic origin. Describing the Bottaccione section at Gubbio, which all others consider to be entirely pelagic, Wezel<sup>40</sup> says: "Except for some lamination, calcareous beds do not seem to exhibit obvious turbidite structures. Bedding-parallel stylotites and recrystallization obli-terated the possible structures." Nevertheless, he infers a "turbidite distal setting for the calcilutites of Bottaccione". He suggests that a 350-m sequence of foram-coccolith limestones, showing a normal 50 Myr sequence of foraminiferal biozones<sup>4</sup> is composed entirely of turbidites, when there has been no report of any turbiditic feature. A more probable conclusion is that the Scaglia Rossa is a pelagic sediment in which there are local intercalations of calcareous turbidites.

All palaeontologists who have studied the Scaglia have recognized an orderly sequence of Upper Cretaceous to Middle Eocene foraminiferal zones<sup>1-7</sup>. Even Wezel<sup>40</sup> admits that the Scaglia shows a normal "thin section biostratigraphy". If the Scaglia is Miocene, the orderly Cretaceous to Eocene foraminiferal zonation must be explained. Wezel<sup>40</sup> explains the gross normal 'thin section biostratigraphy' with the intervention of an intermediate area of sedimentary accumulation, located between the source area and the final basin of Scaglia Rossa deposition. This means that after deposition of a normal stratigraphic sequence of Cretaceous-Eocene pelagic carbonate ooze, successive layers were stripped off and redeposited by turbidity currents in an intermediate basin. This would invert the order of biozones. Subsequently the process was repeated, so that in the final deposit—the present-day Scaglia—the original order of biostratigraphic zones was restored (Wezel, personal communication, 1979).

Although Wezel<sup>40</sup> states that this is not an extravagant hypothesis, mobilization of turbidity currents simply does not occur by the stripping off of broad but very thin sheets; it is a process which inevitably mixes material from a considerable stratigraphic thickness of the source body. Yet Wezel requires that this happen twice with no increase in the disorder of the sedimentary sequence.

Five sections of Scaglia Rossa, including the Bottaccione section, have been found to contain an abnormal abundance of iridium precisely at the Cretaceous-Tertiary boundary 35,36,39. Similar iridium anomalies occur at the Cretaceous-Tertiary boundary in several other locations (Denmark, at the type

Danian locality<sup>35,36,39,53,64</sup>, southern Spain<sup>54</sup>, northern Spain<sup>55</sup>, New Zealand<sup>39,55</sup>, and the north-central Pacific<sup>64</sup>). As iridium is greatly depleted in the Earth's crust relative to its cosmic abundance, the anomaly has been taken to indicate an influx of extraterrestrial material at the time of terminal Cretaceous extinctions<sup>35,36,39</sup>. If the Scaglia Rossa is really Miocene, it must be coincidence that an iridium anomaly occurs just where the reworked Cretaceous and Palaeocene forams suggest that we are seeing the Cretaceous–Tertiary boundary.

Wezel dismisses the concordant palaeomagnetic results of four independent groups who, since 1973, have measured several thousand samples, and agree that the Scaglia Rossa is an excellent recorder of the magnetic field<sup>8-30</sup>. Umbrian palaeomagnetic directions from Jurassic to Palaeocene define a segment of an apparent polar wander path which, after correction for a tectonic rotation reflecting the overall geodynamic history of the region, is consistent with the reconstructed African polar wander path for that time interval<sup>28</sup>.

The Scaglia Rossa has yielded a magnetic polarity record that exactly matches the seafloor spreading magnetic anomalies in the parts of the ocean known from deep-sea drilling to be of late Cretaceous and early Tertiary age 16,23. Subsequently we have found in the Umbrian sequence an essentially perfect match from anomaly M-4 (Barremian) to anomaly 6C (basal Miocene), an interval of about 100 Myr (refs 29, 30, 46, 47, 63, 65). Furthermore ~80% of this reversal sequence has been checked by measuring more than one section. The same magnetic reversal sequence is found in the Southern Alps, exactly correlated with the biostratigraphic sequence from studies in the Hauterivian through the Maastrichtian Magnetic stratigraphic studies on DSDP Legs 73 and 74 have further confirmed parts of the reversal sequence overwhelming evidence that the Scaglia Rossa is not Miocene.

Wezel's explanation of this polarity stratigraphy is that normal directions occur in thin beds whereas reversed directions occur in thick beds. His Fig. 4 shows columns giving magnetic properties and bedding thickness at Gubbio and he states that they correlate, but we fail to detect any correlation in this figure. The intensity of magnetization of a sediment depends on the concentration of magnetic minerals, which might be related to bedding thickness. However, the direction of remanence is acquired by post-depositional alignment of magnetic grains in water-logged interstices below the sediment-water interface and is independent of the magnetic mineral concentration 10,58-61. Therefore, even if a correlation between remanent intensity and bedding thickness were to be demonstrated, this would be unrelated to the polarity sequence.

If the Scaglia Rossa is Miocene, and if the Scaglia Bianca is correctly dated as Cenomanian (F. C. Wezel, personal communication, 1979), there must be a hiatus of ~80 Myr between the two formations. Wezel indicates that the hiatus is hard to find because the Scaglia Bianca—Scaglia Rossa sequence is paraconformable. We note that the pattern of magnetic declinations and inclinations shows no break in the vicinity of the Bianca—Rossa contact<sup>24,26</sup>, which would be extremely improbable if there were a hiatus of 80 Myr hidden in the sequence. Moreover, 100 m of normally polarized limestone lie above the Scaglia Bianca—Scaglia Rossa contact<sup>21,23,24,26,29</sup>. This corresponds to the later part of the Cretaceous magnetic quiet zone. There is no equivalent to this long normal zone in the Miocene reversal history<sup>62</sup>.

If the Scaglia Rossa is Miocene, the perfect match between the Umbrian magnetic stratigraphy and the sea-floor anomalies for almost 100 Myr must be another coincidence unless we consider that all of the sea floor currently considered to be of late Cretaceous to Oligocene age is actually of Miocene age. Many DSDP Initial Reports document that this is not the case.

It has been suggested that the Miocene forams between limestone beds at Gubbio might indicate that portions of the Scaglia Rossa are huge osteoliths. The palaeomagnetic stratigraphy shows that this is not the case. Declinations change

slowly and smoothly; they do not show the sudden breaks that should occur at the limits of olistostrome blocks, at least some of which would have rotated during emplacement. Rotations of this kind have been found in several synsedimentary slide masses 5-15 m thick in the turbidite-bearing Furlo section<sup>63</sup>; they are not present at Gubbio, or in any of the entirely pelagic sections which have been studied.

### A reply by F. C. Wezel

Istituto di Geologia dell' Università, I-61029 Urbino, Italy

I thank Alvarez and Lowrie for their comments on my paper on the Scaglia Rossa<sup>1</sup>. However, I found their comments scientifically unsatisfactory for at least two reasons. First, although my work was published two years ago they present no new observed facts. Rather they seem to have adopted a model to which all data must be fitted. Second, although I raised the problem of Miocene foraminifera in the Scaglia Rossa turbidites, I did not, in fact, conclude that they were Miocene in age.

Further, Alvarez and Lowrie seem to have misinterpreted the spirit of my paper. In dispelling the alleged cliché of the Scaglia Rossa as "a conformable, complete and pelagic sequence of oceanic type"2,3, I stressed the rudimentary state of our factual geological knowledge of the formation and the urgent need for

more research "before continuing to pursue other striking speculations remote from facts". It is regrettable that Alvarez and Lowrie have ignored some basic points of my paper contradicting the inferred pelagic origin of the Scaglia Rossa limestones. For example, (1) The palaeogeographic reconstruction indicating a series of narrow and current-influenced troughs in a probable taphrogenic regime, marked by a combination of subsidence and distension. (2) The facies and palaeocurrent analysis showing the distal basinal environment of the Bottaccione section. (3) The basin-wide regional megarhythmicity of the vertical sequences, expressing temporal changes in sedimentation rate as a consequence of the structural activity of the passive margin tectonics.

The micropalaeontological data of Coccioni (personal communication) clearly show the presence of Miocene foraminifera in clay interbeds from various sections of the Scaglia Rossa. This work was carried out in our laboratory by painstakingly washing 400 kg of sample; 238 Miocene foraminiferal tests were recovered. Alvarez and Lowrie's statement that "not a single Miocene foram was found . . . in detailed examination of about 200 thin sections of Scaglia limestone beds from six localities ... ", is not at all surprising. It rather pinpoints the methodological inadequacy of thin section studies. The presence of Miocene microfossils represents undoubtedly a real problem which has not yet been solved. With our current knowledge, I am now inclined to believe that the Scaglia Rossa is probably Cretaceous-Eocene in age, but complete disregard of the observed younger foraminifera is not an adequate solution to the problem.

Alvarez and Lowrie did not take into account a vast fund of geological information. They state once more the presence of an anomalously high iridium concentration at the Cretaceous-Tertiary boundary in the Bottaccione and other four sections of Scaglia Rossa. They stated that "No iridium anomaly is yet known at any other level in any pelagic sediment". Possibly one could believe in such "iridium anomaly" after many analyses have been undertaken in other beds of the sedimentary column (see ref. 4). Unfortunately, however, the concerted effort of the catastrophists<sup>5-7</sup> focused almost exclusively on the 'magic' thin Cretaceous-Tertiary boundary clay. In such conditions, without a thorough and detailed examination of numerous other clay interbeds and consideration of the minero-petrographic and geochemical contexts, it would be wrong to interpret a unique event as a catastrophe.

Some very significant recent results have now demonstrated other iridium anomalies at different levels. For example, a series of analyses carried out on the 1-m thick cherty black shale ('Bonarelli level', considered Turonian in age), located ~ 240 m under the Cretaceous-Tertiary boundary, has unequivocally shown an anomalously high iridium concentration, about twice as great as the K/T clay8. Recent geochemical and petrographic investigations9 suggest that this iridium anomaly could be imputed to volcanic activity and not to a second even more drastic extraterrestrial catastrophe.

Finally, I should like to re-emphasize the crude relationship I observed between magnetic properties and variations in lithology. Palaeomagnetic data from the thick coarser-grained turbidites may be controlled by depositional currents, whereas those from the finer-grained beds may more accurately record the Earth's magnetic field.

Therefore the conclusions by Alvarez and Lowrie do not seem to be supported by adequate facts and thus the 65-Myr catastrophic event may be considered an imaginative but unproven hypothesis. I therefore urge, once again, a critical assessment of the different aspects of the Scaglia Rossa geology.

## Population trends among Jamaican reef corals

James W. Porter\*, Jeremy D. Woodley†, G. Jason Smith\*, Joseph E. Neigel\*, James F. Battey\* & Dorinda G. Dallmeyer\*

\* Department of Zoology, University of Georgia, Athens, Georgia 30602, USA

Disturbance has been cited as a potentially important agent in structuring ecological communities by modifying the effects of competition1-5. Catastrophic disturbance has also been proposed as a factor promoting the coexistence of competing species in highly diverse tropical ecosystems such as rain forests and coral reefs<sup>2,6-11</sup>. Here we describe patterns of recruitment and mortality among reef corals over 4 yr at several depths on the reefs of Discovery Bay, Jamaica, which were struck by Hurricane Allen on 6 August 1980<sup>12</sup>. Photographic quadrats monitored since 1976 on a shallow water reef showed a negative correlation between coral abundance and mortality which was not offset by compensatory patterns of recruitment. This slow trend in the disproportionate reduction of rarer, competitively inferior species was reversed by Hurricane Allen, with storminduced mortality being greatest in the most abundant species. On deeper reef stations, undisturbed by the storm, slower rates of colony loss were compensated for by commensurate rates of colony recruitment. Thus, patterns of differential mortality and recruitment contribute to the maintenance of high species diversity in this tropical marine ecosystem.

Photographic stations were established on Monitor Reef, on the West Fore Reef of Discovery Bay, a well studied area<sup>13</sup> of classic Caribbean reef morphology<sup>14,15</sup>, in September 1976, and were rephotographed biennially until 1980 (Fig. 1). Photographs were analysed for per cent cover, species number and relative abundance within the plots, recording the fates of 1,718 individual coral colonies in 24 species with respect to recruitment, whole and partial mortality, and growth.

Reef-building corals are photosynthetic and compete to secure space for the interception of both light and plankton 16-19. Competitive outcomes between neighbouring individuals are determined by differential growth rates, overtopping morphologies and abilities in extra-coelenteric digestion<sup>2</sup> Before Hurricane Allen, mortality among shallow water corals from photostations II (3.8 m depth) and IV (6.7 m depth) was inversely density dependent, with species of lesser abundance suffering proportionally greater percentages of loss due to partial as well as complete mortality of individual colonies (Fig. 2). Recruitment rates were low for all species in shallow water stations; recruitment rates to photostations II, IV and XII of newly arriving colonies which achieved a size of ≥ 1 cm<sup>2</sup> ranged from 0.0 to 1.81 m<sup>-2</sup> yr<sup>-1</sup>, with an average rate for all 24 species in the 4-yr survey before Hurricane Allen of  $0.19\pm0.39~\text{m}^{-2}~\text{yr}^{-1}$ . In addition, the disproportionate rate of loss among the rarer species was not offset by compensatory recruitment patterns. These data suggest that in the absence of a major perturbation, there is a tendency for shallow-water communities to become monopolized by the branching Acropora species, causing a reduction of diversity with time.

Hurricane Allen was the second strongest recorded in the New World this century<sup>12,23</sup>. It was designated as a 5 on the International Hurricane Scale (there is no 6), with central pressures of 899 mbar and maximum wind speeds of 285 km h<sup>-1</sup> (ref. 24). The north coast of Jamaica, normally sheltered from severe storms<sup>25</sup>, received storm waves ranging from 6 m height over the phototransect area to 12 m height on less sheltered

reefs on the eastern side of the bay. (The last hurricane with similar track to Allen was in 1917<sup>26</sup>. However, disturbance sufficient to set back *Acropora* dominance may occur in severe winter storms at greater frequency.) Damage to corals varied with their depth of attachment, exposure to impinging waves, skeletal tensile strength and morphology<sup>23</sup>. Analysis of the storm effects in the phototransect areas reveals that in water less than 10 m deep, mechanical disturbance from fracture, scour and toppling reduced living coral cover from 51–54% to 10–12%. Mortality was greatest among the branching, friable and loosely attached *Acropora* species<sup>27–29</sup> which numerically and areally dominated the pre-hurricane reef. During the first 4 yr of the survey, we documented an increase in dominance by these species, a trend which was reversed during Hurricane Allen (Fig. 2). This reversal in mortality patterns does not result from

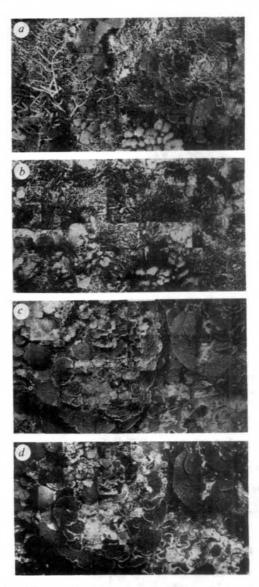

Fig. 1 a, Photostation IV at 6.7 m depth, Monitor Reef, Discovery Bay, Jamaica, 28 September 1976; b, same station, 14 August 1980, 8 days after Hurricane Allen. c, Photostation XII in 32.3 m depth, Monitor Reef, 1 October 1976; d, same station, 14 August 1980, post-Hurricane Allen. Photostation montages shown are constructed from 32 individual 0.5 × 0.5 m photographic frames that cover a 2 × 4 m plot; 8 m² is sufficient to define per cent cover, relative abundance, cumulative species number and average number of colonies per m² such that a doubling of this sample size would not be expected to change the value of the measured parameter by more than 5% (ref. 34). In comparing a and b, note the differential removal of the spatially dominant branching Acropora species and the creation of a pavement of fragmented coral branches.

<sup>†</sup> Discovery Bay Marine Laboratory, University of the West Indies, PO Box 35, Discovery Bay, Jamaica

Acropora commonness per se but from its morphology and concomitant susceptibility to wave damage.

In the deeper reef station (PS XII, 32.2 m depth), our detailed analysis did not reveal any effects of the storm (Fig. 1c, d). In the 4 yr before Hurricane Allen, no apparent relationship existed between the per cent cover of a coral species and the likelihood that it would loose or gain area in a subsequent survey; nor did this pattern change in the immediate post-hurricane survey. Recruitment patterns have not varied from year to year in the deep reef station, but, in contrast to recruitment patterns in shallow water which showed no relationship between loss and recruitment, there is a highly significant (Spearman rank correlation  $r_s = +0.55$ ; 0.01 > P > 0.005) positive correlation between the loss of colonies and their recruitment into the deeper reef station.

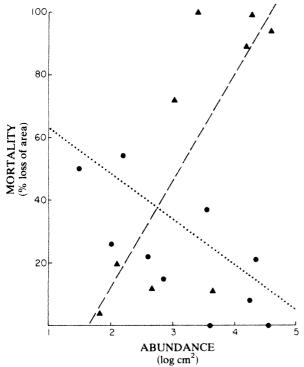

Fig. 2 Loss of existing area by each species in a subsequent survey ( September 1976 to September 1978, pre-Hurricane Allen; A. September 1978 to August 1980, post-Hurricane Allen) is plotted against the abundance of that species in shallow-water photostations II and IV. Photographs are analysed from area covered by each separate colony with a Hewlett-Packard 9815A-9864A digitizer. Mortality was measured as the disappearance of colony area from one survey to the next and includes mortality from physical factors, disease, predation, extra-coelenteric digestion and occlusion from the camera's eye due to the overgrowth of one species by another. We assume overtopping reduced fitness of fully shaded lower individuals and have demonstrated in photostations II and IV that the removal of canopy branches of Acropora palmata reveals many dead coral colonies which were living just before being overtopped between 1976 and 1980<sup>23</sup>. Mortality was negatively correlated with abundance for the years preceding Hurricane Allen (Spearman rank correlation  $r_s = -0.74$ ; 0.01 > P > 0.005; n = 10). While all species lost some area during the storm, the pre-hurricane pattern of disproportionate loss among the rarer coral species was reversed, with natural selection significantly favouring corals of lesser abundance ( $r_s = +0.65$ ; 0.05 > P >0.025; n = 9). Trend lines are determined by linear regression. Rank order for adequately sampled coral species (three or more colonies and at least  $1.0\times10^2~\text{cm}^2$ ) for photostations II and IV for both years is: A. palmata (PS II), Acropora prolifera (PS IV), A. palmata (PS IV), Montastrea annularis (PS IV), Acropora cervicornis (PS IV), Agaricia agaricites (PS IV), A. agaricites (PS II), Porites astreoides (PS II), M. annularis (PS II) and Millepora complanata (PS IV). The rarest species included in the initial survey (1976-78), M. complanata, was too rare to sample adequately in the subsequent survey (1978-80) because it was almost completely overgrown by 1978.

Hurricane Allen has produced a complex biological and morphological rearrangement on the Jamaican reef, in striking contrast to the original organization. Before the storm, shallow water mortality was strongly influenced by biological controls of competition through overgrowth; during the storm, mortality was predominantly controlled by physical factors, with heaviest losses among the commonest, competitively superior (but with respect to the storm, morphologically inferior) species. Hurricane Allen has temporarily eliminated overtopping as a significant agent of mortality in shallow water Jamaican reefs. Although patterns of mortality reversed during the storm, it must be kept in mind that the post-hurricane shallow reef retains slightly less than 10% of the orginal coral cover, and the predictive model (exemplified by Fig. 2) that diversity will increase until crowding slowly reduces it, remains untested by recovery data. Despite the proven regenerative powers of coral fragments<sup>29-32</sup>, in the period following the hurricane there has been a high mortality among Acropora branchlets tagged or photographed immediately after the storm<sup>33</sup>. It remains to be demonstrated whether any of these asexually produced pieces will survive to contribute significantly to the regenerating reef.

In deeper water, more equitable competitive abilities among species and slower growth rates could retard competitive exclusion, allowing lower disturbance levels to act successfully as diversifying forces<sup>2,4,7</sup>. Compensatory processes of recruitment, quantified in the present study, might also promote species richness.

This report is part of a long-term study of changes in community structure. It contrasts those changes occurring under the slow influence of continuously acting or chronic factors with those due to sudden but rare catastrophic disturbances. We are continuing to document the successional dynamics of recovery after this natural experiment so as to quantify better the mechanisms by which patterns in these communities arise, persist or change.

## Evidence for delayed mortality in hurricane-damaged Jamaican staghorn corals

§ 1 Goffe St, Box 35, Hadley, Massachusetts 01035, USA

Severe tropical storms can cause widespread mortality in reef corals<sup>1,2</sup>. The Caribbean staghorn coral, Acropora cervicornis, although dependent on fragmentation for asexual propaga-, is particularly vulnerable to hurricane damage<sup>6,7</sup> most important agents of post-hurricane mortality are assumed to be high wave energy and change in salinity, factors which typically soon diminish in intensity. We report here that there was substantial delayed tissue and colony death in A. cervicornis on a Jamaican reef damaged by Hurricane Allen. This previously undocumented degree of secondary mortality, sustained for 5 months and unrelated to emersion9, was over one order of magnitude more severe than that caused by the immediate effects of the storm. The elimination of >98% of the original survivors suggests potentially complex responses to catastrophes, involving disease 10,11 and predation, which may explain the widely variable rates of reef recovery previously reported 12-15.

Hurricane Allen passed within 65 km of the reefs of Discovery Bay on 6 August 1980 (refs 7, 16). This storm, the strongest recorded for the Caribbean, generated massive waves (>6-12 m) but little rain<sup>7</sup>. The large mounds of the delicately branching A. cervicornis, which had dominated the West Fore Reef between 6 and 20 m depth<sup>4,17</sup>, were extensively fragmented<sup>7,16</sup>. To assess the long-term effects, we surveyed all pieces of A. cervicornis having living tissue in three haphazardly chosen 1-m<sup>2</sup> areas of moderate to severe damage at 8 (n = 125)and 14 (n = 129) m depth on Dancing Lady Reef 3-9 days after the storm. These pieces were all detached by the hurricane, the skeletal break often (53%) occurring where there had been no living tissue<sup>4</sup>. Although the once open network of branches was compacted, much of the surviving tissue was not smothered by direct contact with other fragments or the underlying solid reef base. The median number of living or partially living branches per fragment was 3 (range 1-19), and 53% of the fragments had at least one living axial (terminal) polyp (median = 1, range 0-17). The median total length of living tissue in these quadrats was 916 (range 457–1,250) cm  $m^{-2}$ , ~40% of 1977 estimates<sup>1</sup> We individually tagged each living staghorn in the six quadrats and returned at irregular intervals to re-examine them.

Mortality continued at an unexpectedly high rate (Fig. 1). For censuses made within 4 weeks of the storm, there were highly significant differences at both depths (after tagging) between surviving and dead colonies in the lengths (when tagged) of their longest living branches (P < 0.001, Mann-Whitney U test), but this difference showed reduced significance by 7 weeks (P < 0.03) and was absent by 12 weeks (P > 0.1). The relationship between the total number and presence of axial polyps on the longest living branch and survival was not strong (0.05 > P > 0.01 at any depth for one census only). Other attributes (depth, branching order<sup>19</sup>, number of live branches, orientation of longest living branch and relative height of fragment off bottom) showed no significant relationship with survival. Five months after the storm, we found only four living colonies within the six

quadrats, and median total length of living tissue was reduced, from 916 to 10 (range 0-26) cmm<sup>-2</sup>. Thus there had been a nearly 100-fold long-term decrease in living colonies from the original post-storm number. Examination of other areas on Dancing Lady and other Discovery Bay reefs indicated that our quadrats were not atypical.

Two 18-m<sup>2</sup> transects were established near the shallow and deep sites following the death of most of the originally tagged corals by January 1981. Surveys of these transects showed that, in some areas, tissue mortality still exceeded new growth (indicated by lengthening branches and production of new axial polyps) nearly 1 yr after the hurricane. At 8 m depth there was a 26% reduction in live tissue (from 27 to 20 cm m<sup>-2</sup>) between mid-March and late July, while at 14 m depth there was an increase of 11% (from 26 to 29 cm m<sup>-2</sup>). In both transects the number of living fragments had declined during this interval (from 25 to 17 at 8 m, and from 23 to 17 at 14 m).

There are many possible explanations for this delayed mortality. Fragmentation might (1) facilitate continuing abrasion by the rolling of free fragments<sup>12</sup>; (2) decrease the 'three-dimensionality' of the reef, resulting in smothering or easier access for benthic predators of corals<sup>4</sup>; or (3) increase the susceptibility or exposure of colonies to disease 10,11. A. cervicomis could be particularly susceptible to these processes because of its growth form, sensitivity to stress (for example, extreme temperature 20,21 and low salinity8), and its apparently high vulnerability to disease 11 (perhaps partly a consequence of its tendency to form large stands, hence increasing the potential for epidemics<sup>22</sup>). Differential initial mortality of staghorn coral and its predators, competitors<sup>23</sup>, prey and pathogens could upset pre-storm relationships, leading to the coral's sharp decline. Some of these mechanisms seem to have had no major effect: we observed little evidence of burial by sediment or continuing mechanical abrasion, even on days with large swells. There was no obvious, long-term increase in competition with algae; species which showed 'blooms' within a month of the hurricane have since died back.

During the first few months, much of the mortality was probably related to continuing disease and fragmentation stress. Unusual amounts of tissue exfoliation, resembling that termed the white band disease' were observed in some colonies of A. cervicornis for 2 months before the hurricane. This exfoliation continued after the storm, and could not be reliably distinguished from predation (see below) for at least 1 month. Although a relationship between fragmentation and disease has been reported for A. cervicornis in Curacao. We found no persistent relationship between survival and fragment length, orientation or elevation. There is, moreover, some evidence for delayed post-hurricane mortality in species of Acropora not showing extensive tissue loss beforehand (Acropora palmata in Jamaica and Acropora prolifera in St Croix; R. D. Clarke, personal communication).

By January 1981 mortality was primarily related to the activities of species that were previously important sources of

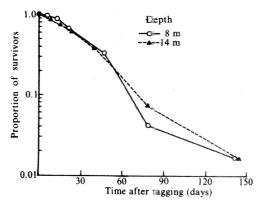

Fig. 1 Proportion of fragments surviving as a function of the time elapsed after tagging. Each fragment had one or more patches of living tissue, and was tagged 3-9 days after the hurricane.

0028-0836/81/470251---02\$01.00

Table 1 Estimates of mean predator densities (per m<sup>2</sup>) before and after Hurricane Allen

	Density (m <sup>-2</sup> )	
Depth,	(Before	(After
Location	hurricane)	hurricane)
8 m, DL	13.5 (30)	8.4 (16)
14 m, DL	6.0(30)	2.6 (25)
14 m, DL	1.8(30)	1.3(25)
9 m, LTS	0.6(40)	0.3(25)
14 m, DL	0.6 (40)	0.1 (200)
	Location 8 m, DL 14 m, DL 14 m, DL 9 m, LTS	Depth, (Before hurricane)  8 m, DL 13.5 (30)  14 m, DL 6.0 (30)  14 m, DL 1.8 (30)  9 m, LTS 0.6 (40)

Reefs surveyed were Dancing Lady (DL) and LTS (reef immediately west of DL); numbers in parentheses indicate numbers of 1-m<sup>2</sup> areas examined. The only values available for before the hurricane are based on surveys by Kaufman<sup>24</sup> (1977; *Diadema, Eupomacentrus*) and L. S. Land (unpublished results, 1975; Coralliophila), but these seemed to be representative of pre-storm conditions in 1980. 'After' densities were assessed in February-March 1981.

mortality in Discovery Bay. Predation by the snail Coralliophila abbreviata 4,24,27 has been particularly severe in shallow water; 1-m<sup>2</sup> quadrats along the transect at 8-m depth containing living staghorn and snails in May showed a median decrease by July in total staghorn length of 27.5 cm, whereas quadrats containing coral but no C. abbreviata showed a median increase of 2 cm (P < 0.01, Mann-Whitney U test). Disturbance by the urchin, Diadema antillarum<sup>24,25</sup>, and the damselfish, Eupomacentrus planifrons<sup>24</sup>, has also contributed to the observed coral deaths. In March, densities of these species were generally lower but within an order of magnitude of pre-storm estimates (Table 1), in contrast to the 100-fold decrease suffered by the staghorn. Thus predation pressure per colony of surviving A. cervicornis is now substantially higher.

Several important points emerge from this study. First, future studies of catastrophic damage to reefs (and other ecosystems) should be started as soon as possible after the event. By 5 months, for example, many tagged dead pieces had eroded calices, thus this characteristic<sup>14</sup> could not by then be used to distinguish between pieces dying before and after the storm<sup>2</sup> Second, the geographical and temporal scale over which catastrophes occur could critically influence subsequent events. For example, destabilization of relationships between corals and their predators is more likely to occur when the area of coral destruction is great; adult predators of limited mobility, unable to emigrate from decimated regions, will continue to feed in areas where new coral growth can no longer keep pace with predation. The resulting drop in coral abundance will be particularly severe if predators do not succumb rapidly to starvation. Similarly, when substantial coral mortality (for whatever reason) occurs only rarely, the relative abundances of associated reef organisms are more likely to be strongly shifted28. Thus survival probabilities and regeneration rates observed after routine levels of fragmentation (experimental or natural<sup>4,5,11</sup>) may tell us little of the reef's potential for recovery from unusually exten-

We thank L. Kaufman, B. Keller, V. Tunnicliffe and J. Woodley for help in the field; B. Keller for assistance with the analysis; and J. Jackson, C. Badgley, L. Buss, E. Chornesky, R. Grosberg, K. Rylaarsdam and H. Schuhmacher for comments on the manuscript. This work was supported by NSF grant BNS-7904747 to N.K., and by studentship to M.C.R. from the Inter-University Council, London. ## Carbon-13 isotopic fractionation as a measure of aquatic metabolism

#### S. V. Smith\*‡ & P. Kroopnick†

- \* Hawaii Institute of Marine Biology, PO Box 1346, Kaneohe, Hawaii 96744, USA
- † Hawaii Institute of Geophysics and Department of Oceanography, University of Hawaii, Honolulu, Hawaii 96822, USA

The fixation of dissolved CO<sub>2</sub> in organic matter during photosynthesis preferentially removes 12C from the water, causing the remaining HCO<sub>3</sub> to become enriched in the less abundant isotope, <sup>13</sup>C. Respiration later releases part of this CO<sub>2</sub> back into the water. Metabolically active aquatic communities thus can generate variations in both the chemical1-3 and isotopic compositions of the water surrounding them. We describe here experiments designed to establish the isotopic fractionation of carbon by the metabolism of two common coral reef organisms. We then show that the fractionation coefficient obtained for the metabolism of those organisms is also applicable to a reef community and may be used to estimate the metabolic rate of the community.

In our first experiment, we placed specimens of the common Indo-Pacific reef-building coral, Pocillopora damicornis, in a 90-litre aquarium and alternately placed the aquarium in sunlight and darkness during a 6-h period. The aquarium was covered with a sheet of clear plastic (Mylar) to impede gas exchange across the air-water interface. Samples were collected for measurement of pH and alkalinity and calculation of ΣCO<sub>2</sub> (ref. 8), and duplicate samples were processed for carbon and oxygen isotopic analyses9. We shall consider here only the carbon data. The isotopic data are reported in the familiar  $\delta$  notation:  $\delta^{13}C = [(R_{\text{samp}} - R_{\text{std}})/R_{\text{std}}] \times 1,000$  where R is the ratio  $^{13}C/^{12}C$  and  $\delta^{13}C$  is reported in parts per thousand (%) relative to PDB. The second experiment was similar, except that we used the common reef-flat red alga, Acanthophora specifera, and the incubations occurred over a 24-h period.

In the third experiment, water samples were collected from a coral reef in Kaneohe Bay, Hawaii, over a mixed algal/sand community in water about 3 m deep. Procedures were similar to those used for the two aquarium experiments, except that the water over the reef community was open to gas exchange with the atmosphere. The observed range of  $\Sigma CO_2$  variation in the field experiment was about 80 µmol l<sup>-1</sup> compared with 300 µmol 1<sup>-1</sup> in the aquarium experiments. Water flow across the reef is typically < 5 cm s<sup>-1</sup>. Therefore samples were collected at one location at selected 1-h intervals over a 24-h period.

Consider the simplified metabolic reaction:

$$CO_2 + H_2O = CH_2O + O_2$$
 (1)

<sup>‡</sup> Present address: Department of Zoology, University of Western Australia, Nedlands, Western

The progressive utilization of  $\Sigma CO_2$  as the reaction proceeds from left to right represents photosynthesis and should be described by a change of  $\delta^{13}$ C as a function of decreasing  $\Sigma$ CO<sub>2</sub>. Similarly, respiration (the metabolic reaction proceeding from right to left) should be described by a change of  $\delta^{13}\bar{C}$  as a function of increasing  $\Sigma CO_2$ .

Broecker and Oversby 10 demonstrate the use of the Rayleigh distillation equation to describe the progressive change in the isotopic composition of some material, X, as that material is removed from the initial dissolved phase,  $X_0$  according to a single-stage fractionation model:

$$\frac{R_X}{R_{X_0}} = f^{\alpha - 1} \tag{2}$$

where  $R_{x_0}$  is the starting isotopic ratio,  $R_X$  the isotopic ratio in the dissolved phase at any time during reaction, f the proportion of X remaining in the dissolved phase at that time in the reaction and  $\alpha$  the fractionation coefficient. Equation (2) can be rewritten in a form that is convenient for numerical computation:

$$\Delta \delta_X \approx \varepsilon \ln f \tag{3}$$

where  $\varepsilon = 1,000 \ (\alpha - 1)$  and  $\Delta \delta_X$  represents the change in the  $\delta^{13}$ C of the  $\Sigma$ CO<sub>2</sub> in solution. Thus,  $\Delta\delta_X$  versus ln f should have a slope  $\varepsilon$ . At any point in a Rayleigh distillation, the product material will differ from the remaining material by approximately  $\epsilon \%$ .

'Reverse distillation' (the release of CO<sub>2</sub> from organic matter to the dissolved phase) may follow the distillation line if the material utilized is released without fractionation. This condition need not apply, although it applies here to the carbon metabolism data.

In the case of calcifying organisms, such as corals, or calcifying communities, such as coral reefs, variations in  $\Sigma CO_2$  and  $\delta^{13}C$  of  $\Sigma CO_2$  reflect both calcification and organic metabolism. The  $\delta^{13}C$  of coral reef CaCO<sub>3</sub> is near the  $\delta^{13}C$  of  $\Sigma CO_2$  in seawater (0 to -5%; see, for example, ref. 11), whereas the  $\delta^{13}$ C of organic material from coral reefs is about -14 to -18% (ref. 12). Moreover, calcification ordinarily induces CO<sub>2</sub> changes substantially smaller than CO<sub>2</sub> changes from organic carbon metabolism<sup>6,8</sup>. We conclude that, as calcification is a weakly fractionating reaction, we can compare  $\delta^{13}C$  with calcificationcorrected  $\Sigma CO_2$  as an indicator of organic metabolism (calcification correction is  $\Delta$  total alkalinity/2)<sup>6,8,13,14</sup>.

Figure 1 describes the relationship between  $\Delta \delta^{13}$ C and calcification-corrected  $\Sigma CO_2$  (expressed as the fraction remaining), as determined by the aquarium experiments. Note that for CO<sub>2</sub> released during respiration, the data are described by the same regression relationship as the distillation, or uptake, curve. For this  $\delta^{13}$ C fractionation,  $\varepsilon$  is -18.6% ( $\sigma = 0.7\%$ ).

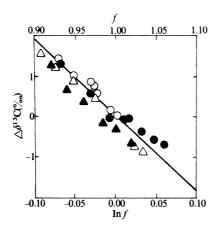

Fig. 1 Relationship between the change in  $\delta^{13}$ C ( $\Delta \delta^{13}$ C) and the fraction of calcification-corrected ΣCO<sub>2</sub> remaining {[CO<sub>2</sub>- $(\Delta \ alk/2)]/CO_2 \ initial\} \ in \ laboratory \ incubations \ of \ corals \ (light,\bigcirc;$ dark lacklose) and algae (light,  $\triangle$ ; dark, lacklose). The geometric regression line is  $\delta^{13}C = 0.04 - 18.6 \ln f$ .

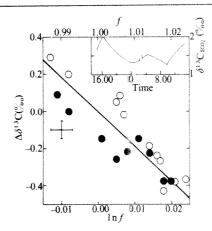

Fig. 2 Relationship between  $\Delta \delta^{i3}$ C and the fraction of calcification-corrected  $\Sigma CO_2$  remaining from field experiment on algal-coral reef community. Also included is the variation of the  $\delta^{13}$ C of the  $\Sigma$ CO<sub>2</sub> as a function of the time of day. The offset between midnight and 5 a.m. represents new water from outside the reef. Note the 5× scale expansion relative to Fig. 1. The cross represents the analytical precision of the measurements. The line through the data is that calculated for the laboratory experiments. O, Light; O, dark.

We offer the following independent estimate of the carbon isotopic fractionation coefficient. During our experiments, the seawater  $\Sigma CO_2$  had an average  $\delta^{13}C$  of  $\sim 2\%$ ; a fractionation of -19% would result in the tissue having a  $\delta^{13}$ C of about -17%. This is in agreement with observed values of -14 to -18% (ref. 12).  $\delta^{13}$ C can be routinely measured with a precision of  $\pm 0.03\%$ . The ΣCO<sub>2</sub> content of seawater is about 2,000 μmol l<sup>-1</sup>. The precision with which  $\Sigma CO_2$  changes can be inferred from isotopic changes is calculated from equation (3) to be about 3 umol 1

Figure 2 shows the data from the field experiment. The geometric regression slope derived from the field data (-18.8) is virtually identical with the laboratory data (-18.6). Daytime  $\delta^{13}$ C increases and night-time  $\delta^{13}$ C decreases average ~0.09%  $h^{-1}$ . Using  $\varepsilon = -19$  and the  $\Sigma CO_2$  of seawater = 2,000  $\mu$ mol  $l^{-1}$ , solving equation (3) gives an average rate of change of  $\Sigma CO_2$  of  $-9 \mu$ mol  $l^{-1} h^{-1}$  in the daytime and  $+9 \mu$ mol  $l^{-1} h^{-1}$  at night. Summing the daytime rate over 12 h and multiplying by 3 m water depth yields a daytime production rate for the entire water column of 3.9 g C m<sup>-2</sup> day<sup>-1</sup>. A 24-h summation for the night-time rate data yields a respiration rate of 7.8 g C per m<sup>2</sup> per day. Gross production is calculated as half the 24-h respiration plus the daytime production, or 7.8 g C per m<sup>2</sup> per day<sup>15</sup>. These figures are close to previous estimates<sup>6</sup> that coral-reef organic carbon production is 5-10 g C per m<sup>2</sup> per day.

We conclude that natural 13C isotopic changes can be used to calculate aquatic metabolic rates. We have measured the fractionation coefficient for this process by inducing relatively large composition changes in laboratory aquaria and then have validated our model with field data. It should be possible to apply this approach to a variety of biological communities.

We thank Alvin Sunn and Ted Walsh for technical assistance.

### Bacillus anthracis on Gruinard Island

R. J. Manchee, M. G. Broster, J. Melling\*, R. M. Henstridge & A. J. Stagg

Chemical Defence Establishment, Porton Down, Salisbury, Wiltshire SP4 0JQ, UK

\* Public Health Laboratory Service Vaccine Research and Production Laboratory, CAMR, Porton Down, Salisbury, Wiltshire SP4 0JQ, UK

During the Second World War, trials of Bacillus anthracis as a potential agent of biological warfare (BW) were carried out on Gruinard Island off the west coast of Scotland (57°56' N. 5°35' W). Small bombs containing a slurry of spores of B. anthracis were detonated: most were suspended, about 6 feet above ground, from a gantry but one was dropped from an aircraft. The resulting aerosol clouds of spores were observed to pass through lines of sheep tethered at various distances downwind of the detonation site and after a few days several sheep died of anthrax. The lethal nature of BW weapons used in the open had, therefore, been shown; the unfortunate legacy was an island heavily contaminated with the persistent spores of a virulent microorganism. Soil samples were tested annually from 1948 to 1968 and again in 1972 by Ministry of Defence staff and were found to contain viable spores of B. anthracis (unpublished work), although accurate counts were not made. We report here the results of the first full survey of the extent of the contaminated area and the numbers of viable spores of B. anthracis present. The survey, carried out in 1979, shows that areas around the gantry remain contaminated to a detectable level but a much wider surrounding zone of undetectable contamination, possibly containing localized high concentrations of spores, could also constitute a hazard.

The whole island was marked out with a grid system (Fig. 1), soil core samples being taken at each marker by pushing a hollow tube (350 mm long  $\times$  25 mm internal diameter) into the ground to a maximum depth of  $\sim$ 300 mm. In the area close to the side of the gantry, 10 closely grouped cores were taken and a second similar group was collected  $\sim$ 50 m north west of the gantry in an area which had been traversed by the spore clouds. In the laboratory, the cores were expelled from their tubes into glass jars and shaken with twice their weight of 0.1 M phosphate buffer (pH 7.0) for 3 min on a 300 r.p.m. orbital shaker. The soil-buffer mixtures were heated at 60 °C for 1 h to destroy vegetative microorganisms, thus ensuring that only spores would be cultured. After allowing large particles to settle, 0.2 ml of the supernatant fluid was spread on each of five nutrient agar plates (Oxoid) which were then incubated at 37 °C for 24 h.

The growth of the natural aerobic spore-forming soil microflora was so profuse that it was necessary to dilute the soil extract at least 1 in 2 to distinguish colonies of B. anthracis, and consequently the presence of low numbers of B. anthracis spores would probably not have been detected. Colonies on nutrient agar which were suspected of being those of B. anthracis were isolated in pure culture and subjected to various confirmatory tests, phage sensitivity and the 'string of pearls test'2 which is based on the sensitivity of the organism to penicillin. The mouse LD<sub>50</sub> of isolates satisfying the confirmatory tests was determined by inoculating spores intraperitoneally in mice. A comparison between the Vollum laboratory strain (LD<sub>50</sub>, 49 spores; 95% confidence limits 20-91 spores) and isolates from the island (LD<sub>50</sub>, 115 spores; 95% confidence limits 38-270 spores) indicated that the latter had not lost their virulence for mice. Blood smears stained with polychrome methylene blue invariably showed the presence of the vegetative rods of B. anthracis, characteristically dark blue with a pink capsule. B. anthracis was detected in 20 out of 153 soil samples. All the positive samples were taken close to the gantry and at 50 m north west of the gantry; the numbers were small (Table 1) and we did not detect B. anthracis in any of the samples taken at the grid markers.

To confirm and extend the above technique we developed one that uses a selective medium and will detect as little as 3 spores per g of soil (Table 2). This involves mixing Gruinard soil with twice its weight of distilled water and agitating vigorously in a domestic blender for 5 min. The soil slurry was strained through a double layer of cotton gauze and 0.2-ml volumes were spread undiluted on the medium devised by Kniseley<sup>3</sup>, which allowed growth of colonies of *B. anthracis* but suppressed growth of the normal soil microflora. Phosphate buffer pH 7.2, water adjusted

## GRUINARD ISLAND Sampling positions 1979

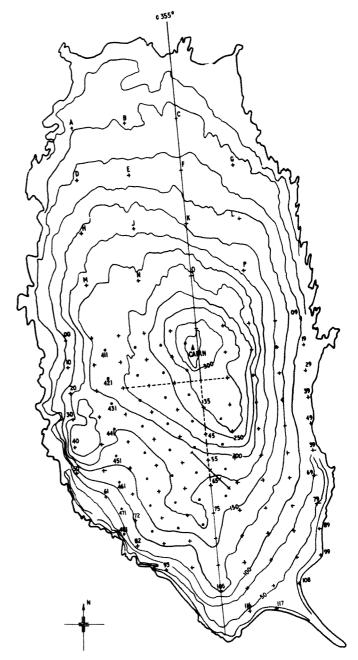

Fig. 1 The northern half of Gruinard Island was subdivided by a 200-m grid represented by the letters A-P, and the southern half by a 100-m grid numbered 00-117. Each cross represents a marker post. The southern grid was further subdivided by placing a marker post represented by ● at the intersections of the diagonals of the 100-m squares and the lines of these posts were numbered 411, 421, etc. The area where BW trials were carried out is indicated by the short line running NW-SE between markers 55 and 65. The gantry location is indicated by the intersect at the SE end of the line and the other intersects represent distances of 50, 100 and 200 yards downwind (scale 1: 10,000).

6-8		30	29	0	2	1
8-14		0	0	0	0	0

Cores collected from the gantry area were sliced into sections 2 cm deep. Each slice was assayed individually for its content of spores of B. - Indicates that the core did not extend to that depth.

to pH values between 5 and 9, and an aqueous solution of 0.1% Tween 80 were also tried as extraction fluids, but no improvements were apparent compared with distilled water. In routine use one viable spore present in a 1-ml sample of soil extract could be successfully cultured. This represents 3 spores per g of soil, equivalent to  $3 \times 10^5$  spores per m<sup>2</sup> of ground. Using the new technique, four times more colonies of B. anthracis were observed than with nutrient agar, and at low levels of contamination (<12 spores per g) B. anthracis was detected by the new technique in samples which otherwise gave negative results.

One of the most important considerations was the distribution of spores with soil depth. Nearly all the viable spores of B. anthracis were found in the top 6 cm of soil (Table 2). This superficial distribution may reflect the slow accumulation of humus on the surface of the soil in this habitat which will delay the rate at which spores become buried.

It has been suggested that in suitable conditions spores of B. anthracis will germinate and proliferate<sup>4</sup>. The presence of small pools of water, neutral to slightly alkaline in reaction, containing decaying vegetation as a nutrient source, and warm weather might encourage the pathogen to multiply. It is our view that such conditions do not occur on Gruinard Island. The soil is acid (pH 4.2-4.7), the native flora slow to decay and the weather generally cool. We have shown that if soil cores are incubated at 37 or 22 °C the spores remain dormant and that spores prepared in the laboratory will not germinate on culture media prepared from extracts of Gruinard Island soil. Although  $\sim 4 \times 10^{14}$ spores were released during the BW trials, the recent surveys have revealed that only a small proportion remain near the surface of the soil. To simulate conditions in which multiplication of these remaining spores might occur, such as the

Table 3 Effect of additions of nutrients on spore counts of B. anthracis

		Incubation	Spore cou	nt per core
Core no.	Nutrient	temperature (°C)	Initial inoculum	Final
1	Blood	37	$5 \times 10^2$	$3.3 \times 10^{9}$
2	Blood	22	$5 \times 10^2$	$3.5 \times 10^{5}$
3	Faeces	37	$5 \times 10^2$	$1.7 \times 10^{3}$
4	Faeces	22	$5 \times 10^2$	$5.7 \times 10^{2}$
5	None	37	$5 \times 10^2$	$3.9 \times 10^{2}$
6	None	22	$5 \times 10^2$	$6.6\times10^2$

Cores (~100 g) from an uncontaminated area close to the gantry were inoculated with about 500 spores of B. anthracis (Vollum) incubated with the indicated nutrient, 5 ml of calf blood or 5 g of rabbit faecal pellets, and assayed for their content of spores of B. anthracis after 7 days' incubation.

nutrient body fluids from a dead animal soaking into the soil, calf blood (5 ml) was added to anthrax-containing soil cores (~50 g) which were then incubated for 7 days at 37 or 22 °C. Addition of blood raised the pH of the soil from 4.5 to 7.2 and after incubation at either temperature these cores showed a large increase in their spore count (Table 3). Other cores supplemented with faecal pellets from rabbits demonstrated a small increase in count only after incubation at 37 °C. It is apparent, therefore, that death of an animal in a contaminated area could provide a favourable growth environment for the proliferation of B. anthracis, and a short period of warm weather would be sufficient to initiate germination followed by growth and formation of a high concentration of second generation spores at the surface of the soil. Such a combination of circumstances would probably be rare but could produce localized high concentrations of the organism close to the soil surface: these have not been found.

Thus, we have developed a technique which will detect B. anthracis spores in Gruinard Island soil at concentrations as low as 3 spores per g of sample, and further work would enable us to define the area contaminated to this level. Nevertheless, it is likely that an area of undetectable contamination would surround such an area. The technique could also be applicable to the examination of soil samples from other localities.

We thank members of Range Section and Defence Microbiology Division of the Chemical Defence Establishment for surveying Gruinard Island, Mr G. N. Wade for technical assistance and Dr J. T. Bartlett, Mr J. A. Carman, Mr G. Harper and Mr K. Allner for advice and helpful discussion.

# Regional accumulation of vegetal pole poly(A)+ RNA injected into fertilized Xenopus eggs

David G. Capco\* & William R. Jeffery

Department of Zoology, University of Texas, Austin, Texas 78712, USA

Cytoplasmic determinants localized in particular regions of the egg seem to be important in cell determination during early embryogenesis<sup>1,2</sup>. Although their composition is uncertain, there is evidence that some are partly composed of maternal RNA molecules<sup>3-6</sup>. Consistent with this possibility, maternal poly(A) RNA and certain specific RNA sequences are reported to show an uneven distribution in the cytoplasm of oocytes and developing embryos<sup>7-11</sup>, suggesting that maternal RNA sequences may contain signals required to distribute themselves in specific cytoplasmic regions of the egg. We have now tested this idea by analysing the distribution of RNA sequences localized in the vegetal pole cytoplasm of Xenopus laevis eggs after microinjection into fertilized zygotes. We report that exogenous vegetal pole poly(A)+ RNA accumulates along a concentration gradient from the vegetal hemisphere to the animal hemisphere of the injected egg and provide evidence that the concentration gradient is set up by active migration of the injected vegetal pole poly(A) + RNA into the vegetal hemisphere cytoplasm between fertilization and the first cleavage.

<sup>\*</sup> Present address: Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA.

Ovulated eggs were orientated and sectioned with a cryotome into six regions through planes perpendicular to the animal-vegetal axis. The sections containing the polar regions of the egg were pooled into animal and vegetal pole groups, their RNA was extracted and labelled *in vitro* by RNA ligase-catalysed transfer of <sup>32</sup>P-cytidine-3',5'-diphosphate to the 3' termini. The labelled RNA was separated into poly(A)<sup>+</sup> and poly(A)<sup>-</sup> fractions and injected into either the animal or the vegetal hemisphere of fertilized eggs ~15-20 min after insemination. The injected embryos were incubated at 18 °C until they reached the proper developmental stage. They were then fixed, processed for histological examination and the distribution of labelled RNA along their animal-vegetal axes was determined by autoradiography.

To ensure that the 3' label was not transferred from the injected RNA to another molecular species, some of the histological sections were treated with enzymes before autoradiography. As shown in Table 1, the number of grains developed in the autoradiographs was not markedly affected by DNase treatment. Grain development was severely decreased,

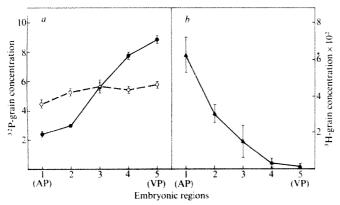

Fig. 1 Grain distribution along the animal-vegetal axis of four-cell embryos after injection of various RNA fractions. Groups of 75-100 dejellied ovulated eggs suspended in a solution containing 20 mM Tris-HCl pH 7.5, 25 mM KCl, 15 mM MgCl<sub>2</sub>, 5% sucrose and 0.1% Triton X-100 (Solution A) were oriented animal hemisphere up, frozen in a dry iceacetone mixture and sectioned with a cryotome into six 200-µm regions perpendicular to the animal-vegetal axis according to the procedure of Moen and Namenwirth<sup>15</sup>. The animal and vegetal pole sections were collected, pooled into separate groups and homogenized (five strokes up and down of a Potter-Elvehjem glass homogenizer with a teflon pestle) in 3 vol of Solution A containing  $15~\mu g\,ml^{-1}$  sodium heparin (4 °C). The homogenate was centrifuged at 10,000g for 10 min at 4 °C, the supernatant fraction was collected and adjusted to 0.5% SDS and to 100 mM with Tris-HCl pH  $9.0^{16}$ RNA was extracted by shaking the suspension with phenyl/chloro-form/isoamyl alcohol (50:50:1). The deproteinized RNA was ethanol precipitated, washed and resuspended (420 µg ml<sup>-1</sup>) in a solution containing precipitated, washed and resuspended (420 µg m<sup>-</sup>/<sub>1</sub> m<sup>-</sup>/<sub>2</sub> solution containing 50 mM Tris-HCl pH 7.5, 10 mM MgCl<sub>2</sub>, 1.5 mM ATP, 6.6 mM dithiothreitol, 1.28 Ci ml<sup>-132</sup>P-cytidine-3', 5'-diphosphate(NeN), and ~230 U ml<sup>-1</sup> of RNA ligase (EC,6.5.1.3, New England Biolabs). The mixture was incubated at 4 °C for 16 h to transfer the labelled nucleotide to the 3' terminus of the RNA substrate<sup>17</sup>. The efficiency of labelling and the integrity terminus of the RNAs upoduct. The elitative of the labelled RNA product was checked by sucrose density gradient centrifugation. RNA labelled to a specific activity of  $\sim 3 \times 10^3$  d.p.m.  $\mu g^{-1}$ was separated into poly(A)+ and poly(A)- fractions by oligo(dT)-cellulose chromatography<sup>18</sup>, ethanol precipitated, dissolved in the microinjection buffer<sup>19</sup> and injected in 30-nl aliquots into the animal or vegetal hemisphere of fertilized eggs (15-20 min after insemination) by the method of Gurdon<sup>19</sup>. The injected volume contained 5-15 ng of poly(A)<sup>-</sup> RNA or the entire oligo(dT)-cellulose-eluted fraction (poly(A)<sup>+</sup> RNA) derived from 5-15 ng of total RNA. Taking into account the specific activity of the injected RNA. the number of grains detected in a section cut through a diameter of the one-cell zygote, and the efficiency of autoradiography, we calculate that ~95% of the injected RNA radioactivity entered the egg. Injected embryos were allowed to develop at 18 °C until the four-cell stage, when they were fixed with Bouins and embedded in paraplast. Sections were cut at 13 µm, extracted with cold 5% trichloroacetic acid, coated with undiluted NTB-2 liquid emulsion (Eastman-Kodak, New York) and exposed for 2 months The developed slides were stained with Harris haematoxylin and examined by dark-field microscopy to avoid confusing the grains with pigment granules<sup>10</sup>. The grains were counted in 400-µm<sup>2</sup> areas spaced at equidistant intervals (usually ~240 µm, but were varied according to the diameter of the embryo). a, O, Represent the distribution of the injected vegetal pole poly and • the distribution of the injected vegetal pole poly(A)+ RNA; b, ▲ represent the distribution of injected 3H-polyuridylic acid (NEN). Animal (AP) and vegetal (VP) regions of the embryo are to the left and right respectively.

however, when the sections were treated with RNase in conditions which hydrolyse both RNA and its poly(A) sequence<sup>12</sup>. Thus the label remains in RNA after injection.

Figure 1 shows the distribution of grains along the animalvegetal axis of four cell embryos injected with various RNA fractions after fertilization. When vegetal pole poly(A)<sup>+</sup> RNA was injected, it appeared to accumulate in a gradient from the vegetal hemisphere to the animal hemisphere with four to five times more grain density in the region nearest the vegetal pole than near the animal pole. Such vegetal to animal hemisphere gradients were observed regardless of whether the vegetal pole poly(A)+ RNA was injected into the animal or vegetal hemisphere, suggesting that the entry point on the egg surface was unrelated to the distribution of the exogenous RNA sequences in the cytoplasm. No significant difference in grain distribution was seen along the other primary axes of the embryos. Two control injections were carried out in parallel with the injection of vegetal pole poly(A)+ RNA. Labelled polyuridylic acid, whether introduced into the animal or the vegetal hemisphere, became distributed along a steep gradient of opposite polarity to that exhibited by the vegetal pole poly(A)+ RNA (Fig. 1), suggesting that the microinjection procedure itself does not dictate the pattern of exogenous RNA distribution. Vegetal pole poly(A) RNA was also injected into fertilized eggs and, in contrast to the poly(A)+ RNA, it showed a relatively homogenous distribution along the animal-vegetal axis of four-cell embryos (Fig. 1).

The results of the vegetal pole poly(A)<sup>+</sup> RNA injections do not necessarily imply that this RNA fraction accumulates along a vegetal to animal hemisphere gradient in a specific fashion. Polyadenylic acid accumulates in a similar gradient after injection into fertilized *Xenopus* eggs<sup>13</sup>, and it is conceivable that the poly(A)+ RNA passively accumulates in the vegetal hemisphere cytoplasm, possibly because of an adventitous association with yolk platelets. To resolve this issue, we injected labelled poly(A)+ RNA from the animal pole region of the ovulated egg into fertilized eggs and analysed its distribution in four-cell embryos. Unlike the vegetal pole poly(A)<sup>+</sup> RNA, the animal pole poly(A)+ RNA did not accumulate primarily in the vegetal hemisphere cytoplasm, but tended to concentrate in the animal hemisphere cytoplasm (Table 2). Others have shown that injected poly(A)<sup>+</sup> globin mRNA also accumulates along a gradient from the animal to the vegetal hemisphere blastomeres in Xenopus embryos 13. These results suggest that the accumulation of vegetal pole poly(A)+ RNA in a vegetal to animal hemisphere gradient is a specific property of the RNA sequences from the vegetal pole region of the egg.

There are three possible explanations for our results: the injected molecules may initially be distributed evenly in the egg and subsequently degraded in the animal hemisphere cytoplasm by localized nucleases; or the injected RNA molecules may be preferentially segregated into the vegetal hemisphere blastomeres by cytoplasmic movements accompanying the second cleavage; or the observed pattern of vegetal pole poly(A)<sup>+</sup> RNA distribution may be due to selective interaction of the injected RNA with specific recognition sites enriched in the vegetal hemisphere regions of the uncleaved zygote and maintained in the four-cell embryo. If region-specific RNA turnover occurs in

Table 1 The effect of DNase and RNase treatment on grain development in embryos microinjected with labelled RNA

Treatment	Grain concentration ± s.d.	% Of control
None	$11.0 \pm 1.4$	
DNase	$10.0 \pm 0.7$	90.9
RNase	$2.1\pm1.4$	18.2

Sections were treated for  $16\,h$  with  $50\,\mu g\,ml^{-1}$  bovine pancreatic DNase I(EC 3.1.4.5) dissolved in  $100\,mM$  Tris-HCl pH 7.5, 3 mM MgCl<sub>2</sub> or  $50\,\mu g\,ml^{-1}$  bovine pancreatic RNase A(EC 3.1.4.22) in  $10\,mM$  Tris-HCl pH 7.5,  $10\,mM$  NaCl,  $1\,mM$  MgCl<sub>2</sub> (refs 8, 12) at 37 °C. Grain counts were made in 400- $\mu m^2$  regions in the central areas of four cell embryos.

Table 2 Grain distribution in the animal and vegetal hemispheres of developing embryos injected with poly(A)+ RNA

			Grain o	concentration	±s.d.
RNA source	Developmental stage	Sample size	Animal	Vegetal	Vegetal/ animal ratio
Animal pole	4 cell	3	$18.0 \pm 1.7$	$9.3 \pm 3.0$	0.5
Vegetal pole	1 cell	4	$20.6 \pm 2.0$	$62.4 \pm 2.4$	3.0
Vegetal pole	4 cell	6	$17.1 \pm 1.3$	$43.8 \pm 1.3$	2.6
Vegetal pole	Blastula	8	$14.6 \pm 3.2$	$23.7 \pm 4.3$	1.6

Animal and vegetal pole  $poly(A)^+RNA$  was derived from different eggs. In the vegetal pole  $poly(A)^+RNA$  experiment, clutches of inseminated eggs were injected with equal amounts of RNA, allowed to develop for the desired time at 18 °C, fixed and processed for histology and autoradiography. Grains were counted in a 400-µm<sup>2</sup> area in the centre of each hemisphere.

the animal hemisphere cytoplasm, we might expect the distribution of injected vegetal pole poly(A)+ RNA between the animal and the vegetal hemisphere regions to be more uniform before the four-cell stage. This possibility was tested by injecting equal amounts of the vegetal pole poly(A)+ RNA into a clutch of fertilized eggs and examining its distribution in embryos killed at various times during early embryogenesis. The accumulation of vegetal pole poly(A)+ RNA in the vegetal hemisphere was more pronounced in the one cell zygote than in the four-cell embryo or the blastula (Table 2), suggesting that the injected RNA is gradually degraded or modified in the vegetal rather than the animal blastomeres during early embryogenesis, perhaps in concert with the relatively high rate of protein synthesis known to occur in the vegetal cells<sup>14</sup>. These results do not support a role for selective degradation of the vegetal hemisphere accumulation of injected vegetal pole poly(A)+ RNA. The unequal distribution of vegetal pole poly(A)+ RNA as early as 20-30 min after injection, when the embryo is still a single cell (Table 2), is also inconsistent with differential segregation to the vegetal blastomeres during the second cleavage.

The formation of a vegetal to animal pole gradient in fertilized zygotes by poly(A)+ RNA from the vegetal pole of unfertilized Xenopus eggs is most simply explained by active migration. Although the possibility that some of the labelled termini of the injected poly(A)+ RNA are exchanged with endogeneous poly(A)+ RNA cannot be excluded, it is highly unlikely that this alone could lead to the observed patterns of labelled RNA.

Our results suggest that vegetal pole poly(A)\* RNA molecules may recognize specific cytoplasmic binding sites which are distributed along a concentration gradient from the vegetal to the animal pole of the egg. These sites could include cytoskeletal elements, membrane systems, specific types of yolk particles or other cytoplasmic organelles. It is not known whether information in the RNA sequence or in endogenous protein that may form complexes with the injected RNA molecules is responsible for this interaction. The ability of maternal RNA molecules or their native ribonucleoprotein complexes to recognize specific regions of the egg is consistent with their being cytoplasmic determinants.

# Sodium and potassium channels in demyelinated and remyelinated mammalian nerve

#### J. M. Ritchie, H. P. Rang\* & R. Pellegrino

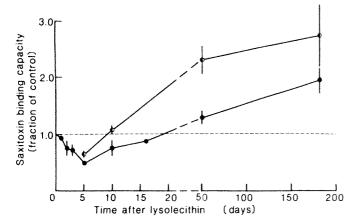

Yale University School of Medicine, New Haven, Connecticutt 06510, USA

Department of Pharmacology, University College London, Gower Street, London WC1E 6BT, UK

Demyelination of peripheral axons initially causes failure of action potential conduction, probably because the internodal membrane lacks sodium channels 1.2. However, Bostock and Sears<sup>3</sup> showed that 3-14 days after demyelination of rat nerve with diphtheria toxin, some axons develop regenerative inward currents in the internodal membrane permitting continuous (non-saltatory) conduction. In nerves that have remyelinated or regenerated, the number of nodes per unit length of fibre characteristically increases greatly<sup>4,5</sup>. As the internodal membrane does not normally possess sodium channels<sup>1,2</sup>, both the earlier appearance of continuous conduction in the demyelinated nerve and the later presence of extra nodes in the remyelinated nerve require either a laying down of new sodium channels or a redistribution of the sodium channels in the original nodes. The present experiments examine the changes in the total number of sodium channels, measured by saxitoxinbinding capacity<sup>1</sup>, that occur in rabbit sciatic nerves which have been demyelinated in vivo with lysolecithin2.5 and then allowed to remyelinate. The results provide no evidence for the formation of new sodium channels during the early stage, when continuous conduction may develop, but show clearly that new channels are formed during remyelination.

Sciatic nerves of rabbits under methoxyflurane anaesthesia were injected on one side in the mid-thigh (20-30 mm distal to the sciatic notch) with lysolecithin (40 µl of a 1% solution under the sheath) and allowed to recover. Reflex function on the affected side was markedly depressed for the first 1-2 weeks, but thereafter recovered. At various times afterwards (1-200 days, see Fig. 1 legend) the rabbits were killed by injection of air into an ear vein, and from each animal both the lysolecithin-treated and control nerves were removed and desheathed. The sodium channel density in 25-30-mm lengths corresponding to the injected region was determined in both the treated and control homogenized nerves from measurement of the saxitoxin-binding capacity<sup>1</sup>. The specific activity of the saxitoxin was initially 7 d.p.m. fmol<sup>-1</sup>, and its radiochemical purity 68%. The mean uptake for the series, 8.4 fmol per mg wet weight, calculated on the basis of the initial purity, is about half that described previously1, because over the several months of these experiments the specific activity declined substantially through backexchange of the label into the water of the solution<sup>1</sup>. Errors from this source, however, were avoided by expressing the uptake by remyelinated nerve relative to that of the control nerve determined at the same time and in identical conditions. Uptakes were usually determined from a labelled saxitoxin concentration of 5 nM, about four times the value of the equilibrium dissociation constant (K) for saxitoxin in this homogenized nerve1. Some experiments, done with 20 nM saxitoxin, gave uptakes about the same as with 5 nM for both normal and lysolecithintreated nerves, confirming that any change in the value of K would not have significantly affected the results.

Histological examination of two nerves at 7 weeks indicated that a large proportion (~70%) of the fibres had remyelinated (and so presumably had originally been demyelinated), as

judged by the observation of single axons, each within its own Schwann cell tube, that were smaller in diameter and more thinly ensheathed with myelin than surrounding normal fibres and those in control nerves; in six nerves examined after 7-10 days there were clear signs of demyelination but little or none of degeneration. It would have been interesting to determine the total number of nodes in the tissue at these times. However, this formidable task was not undertaken, and, unfortunately, no such information is available in the literature. In regenerated rabbit nerve, however, where short internodes are found (at least up to 1 yr after injury), Cragg and Thomas<sup>4</sup> have shown that the average number of nodes per unit length increases 1.4 times for a 10-µm diameter fibre, and almost doubles for the largest (21-22 µm diameter) fibres. Remyelination is known to lead to a similar decrease in internodal length<sup>6</sup> and so, presumably, to a corresponding increase in the number of nodes per unit length.

Initially, the saxitoxin-binding capacity of the lysolecithintreated nerves (expressed per unit weight of desheathed nerve) decreased relative to that of the contralateral controls, but after 2-6 months the binding capacity increased above its control value (Fig. 1). However, the results as expressed in Fig. 1, comparing the binding per unit weight, are distorted by the connective tissue hyperplasia and oedema that follow intraneural injections; and much more significant effects are seen when comparison is made on the basis of binding per unit length as was done in many of the experiments. For example, 5 days after the lysolecithin injection, the weight per unit length of the injected nerve was  $42 \pm 5\%$  greater than in its contralateral control. Thus, expressed per unit weight of nerve, the saxitoxinbinding capacity at this time had fallen to  $0.48 \pm 0.04$  (n = 6), whereas, expressed per unit length of nerve, the fall was only to  $0.65 \pm 0.06$ . Similarly, when saline instead of lysolecithin was injected, after 5 days the saxitoxin-binding capacity expressed per unit weight fell to  $0.77 \pm 0.10$  (n = 4) whereas, expressed per unit length, it remained roughly constant at  $0.96 \pm 0.10$ . However, ligation of a normal nerve ~1 cm distal to the sciatic notch, which involves less surgical interference in the region of the more distal usual injection site, led after 5 days to a fall in channel density in the latter portion of the degenerating nerve that was about the same whether expressed per unit weight or per unit length (to final values of  $0.31 \pm 0.05$ , n = 4, and  $0.33 \pm$ 0.07, respectively). Histological examination of two salineinjected nerves after 5 days showed no grossly abnormal morphology of the myelinated fibres.

The early decrease in binding is difficult to interpret without quantitative information about the amount of fibre degeneration caused by the lysolecithin injection, which the experiments on ligated nerves showed would lead to a rapid decrease in toxin binding. Histological examination showed that little degeneration occurred. Because, in principle, the amount of degeneration might be assessed by measuring binding in distal segments of the nerve sufficiently far down to escape any 'spill-over' demyelination, saxitoxin binding was determined in many experiments in regions both proximal and distal to the injected region. In the region proximal to the lesion in 26 nerves examined 5 days-2 months after injection, the weight per unit length on the injected side and the saxitoxin uptake per unit weight were not significantly different from their control values  $(1.02 \pm 0.05)$  and  $1.04 \pm 0.10$ , respectively). However, in the distal segment the corresponding values were  $1.30 \pm 0.09$  and  $0.95 \pm 0.10$  (n = 17), respectively, showing that some spill-over of the effect distally did indeed occur. Even when the portion of the nerve between the knee and the ankle was examined—a region 40-80 mm from the usual site of injection—there was still an increased binding of saxitoxin (per unit length) of  $47 \pm 13\%$  (compared with a value of  $79 \pm 26\%$  around the injection site) in five nerves that had been injected 7 weeks previously. The morphological basis for this increase remains unclear.

In nerves examined about 2 months after lysolecithin injection, when remyelination was well under way (although not complete because the myelin sheaths were still relatively thin), the weight per unit length was observed to be  $65 \pm 8\%$  greater than in the control. The value of  $1.30 \pm 0.13$  for the channel density of remyelinated nerves shown in Fig. 1 for this time thus corresponds to a value for the sodium channel density per unit length of remyelinated nerve of  $2.31 \pm 0.24$  (n = 13) that of the control. These experiments, therefore, do not support the idea that the source of sodium channels for the extra number of nodes that appear on remyelination is derived from the population of sodium channels in the original nodes. Rather, there is an increased laying down of extra sodium channels in the membrane, consistent with the increased number of nodes, as if the total number of channels per node remains relatively constant.

In some experiments the nerves were mounted in a capillary chamber containing a series of annular platinum electrodes for electrical recording of the monophasic compound action potential, and exposed for 10-15 min to the potassium channel blocking agent 4-aminopyridine. In frog sciatic nerve such treatment leads to a marked increase in the duration of the compound action potential because the blockage of the repolarizing potassium current leads to a broadening of the individual action potentials in each individual fibre (Fig. 2a). However, in normal rabbit sciatic nerve, as already observed in normal rat nerve7, there is at most only a slight broadening of the compound action potential (Fig. 2c, e), presumably reflecting the normal absence of potassium currents<sup>8,9</sup> in all but a small fraction of the fibres. However, after treatment with lysolecithin, rabbit sciatic nerves acquire a distinct sensitivity to 4-aminopyridine (Fig. 2 b, d, f). In five experiments at 7 weeks and three at 6 months the average broadening at half-amplitude, which was  $15.6 \pm 3.5\%$  and  $29.5 \pm 5.1\%$ , respectively, was significantly larger than the broadening of  $3.5 \pm 1.6\%$  (n = 12) of control nerves (P < 0.001). In four experiments at 10 days the broadening of  $7.8 \pm 3.5\%$  was not significant (P > 0.2).

As illustrated in Fig. 2, the compound action potential in the lysolecithin-treated nerve was consistently wider than in the contralateral control; for example, at 7 weeks the action potential was  $47.4 \pm 17.8\%$  broader and conducted  $27.2 \pm 11.0\%$  (n = 5) more slowly. This indicates that the electrophysiological characteristics of the remyelinated axons differ from those of the normal nerve; however, these differences have not been analysed in more detail.

These findings indicate that not only do new sodium channels appear in the remyelinated nodes but also that in the remyelinated nerve, unlike normal nerve (at least 7 weeks-6 months

after demyelination), potassium channels carry part of the current during the action potential. Whether or not these potassium channels are present in newly formed nodes remains unclear, for Sherratt et al. have shown that some rat nodes of Ranvier show signs of paranodal demyelination a few days after diphtheria toxin and are sensitive to 4-aminopyridine. Therefore, one explanation for the sensitivity to 4-aminopyridine in the present experiments would be that the lysolecithin had initially caused a paranodal demyelination of some existing nodes, thus exposing pre-existing paranodal potassium channels, and that it was the 4-aminopyridine sensitivity of persisting damaged original

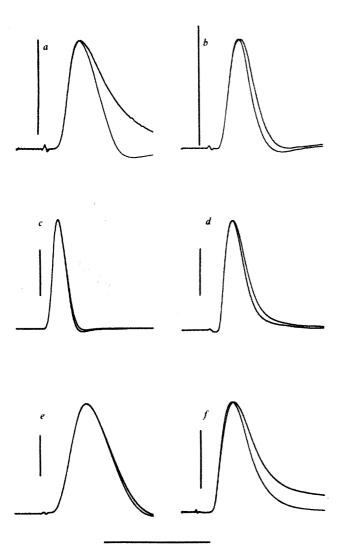

Fig. 2 The effect of 4-aminopyridine on the compound action potential of frog (a) and rabbit (b-f) desheathed sciatic nerves. Each trace consists of a record taken after about 10 min exposure to 4-aminopyridine (200-2,000 µM) superimposed on the control record before exposure; in all pairs the action potential with the longer duration occurs in the treated nerve. Record a is from a frog nerve at 20 °C. Records c and d are from the right and left sciatic nerves, at 37 °C, of a 28-week-old rabbit, whose left sciatic nerve had been injected 7 weeks previously with 40 µl lysolecithin. Records e and f are the corresponding control and treated nerves. at 20 °C, from a 12-month-old rabbit whose left sciatic nerve had been injected with 40 µl lysolecithin 6 months previously. Record b shows another example of the broadening by 4-aminopyridine of the compound action potential, at 37 °C, of the sciatic nerve of a 28-week-old rabbit injected 2 months previously with lysolecithin. The vertical bar in each record represents 1 mV for the control record; the record in 4-aminopyridine has sometimes been scaled downwards slightly so that its amplitude is the same as that of the control to allow the shapes of the action potential to be more easily compared. The horizontal bar represents 1 ms for panels a-e and 2 ms for panel f.

nodes, rather than new nodes, that was observed in the present experiments. Note, however, that for this to account for the results of Fig. 2, any paranodal demyelination existing 7 weeks-6 months after the original exposure to lysolecithin would have to have persisted longer than is generally the case after lysolecithin in other mammals  $^{30-12}$ .

## Receptor binding of somatostatin-28 is tissue specific

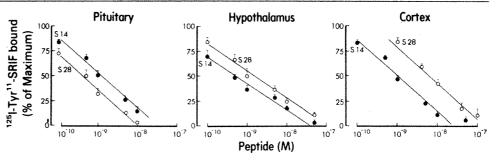

#### C. B. Srikant & Y. C. Patel

Although somatostatin was originally identified in the hypothalamus as a tetradecapeptide (SRIF or S-14)1, subsequent studies have revealed that tissue somatostatin is heterogeneous comprising in addition to S-14 two larger forms with molecular wieghts (M<sub>r</sub>s) of 10,000-15,000 and 3,000 (refs 2-7). Recently a 28-amino acid peptide (somatostatin-28, S-28)-a 14-amino acid N-terminal extension of S-14-has been isolated from mammalian gut and hypothalamus<sup>8-10</sup>. Synthetic S-28  $(M_r, 3,160)$  has been shown to correspond to the 3,000- $M_r$  SLI species found in most tissues<sup>5</sup> and to exhibit greater potency than S-14 for inhibiting both endecrine (growth hormone, insulin, glucagon)<sup>11,12</sup> and exocrine (pancreatic enzymes and bicarbonate) secretion<sup>13</sup>. It is not clear whether S-28 exerts similar effects to S-14 on central nervous system functions<sup>14</sup> nor whether the S-14-like effects of S-28 are mediated through its conversion to S-14 or through direct action on the recently characterized S-14 receptors of rat brain and pituitary membranes<sup>15,16</sup>. We suggest here that the greater potency of S-28 for inhibiting growth hormone secretion is because it binds to pituitary S-14 receptors with 3.2-fold higher affinity than does S-14. Furthermore in the central nervous system, S-28 has a lower affinity than S-14 for the receptors, indicating that it is less potent than S-14 in regulating brain functions. Receptor binding of S-28 in both pituitary and brain occurred directly without significant conversion to S-14, suggesting that S-28 is a true S-14 receptor agonist but possesses distinct tissue specificities.

Membrane fractions enriched in somatostatin receptors were prepared from fresh cerebrocortical, hypothalamic and pituitary tissue obtained from adult male Sprague-Dawley rats using techniques reported previously 13-18. Tyr 11-SRIF was radioiodinated to high specific activity2 and used as the radioligand. Figure 1 depicts the specific binding of <sup>125</sup>I-Tyr<sup>11</sup>-SRIF to S-14 receptors in the pituitary, hypothalamus and cerebral

Fig. 1 Inhibition by S-28 and S-14 of the specific binding of <sup>125</sup>I-Tyr<sup>11</sup>-SRIF to membrane S-14 receptors in the pituitary, hypothalamus and cerebral cortex. Equilibrium binding studies were carried out as described previously  $^{15-18}$  by incubating 50  $\mu g$  membrane protein and  $5\times 10^{-11}$  M  $^{125}$ I-Tyr $^{11}$ -SRIF at 30 °C (40 min for brain membranes and 20 min for pituitary membranes) in 50 mM HEPES-KOH buffer, pH 7.5, containing bovine serum albumin

(BSA, 10 mg ml<sup>-1</sup>), MgCl<sub>2</sub> (5 mM), Trasylol (200 KIU ml<sup>-1</sup>), bacitracin (0.02 µg ml<sup>-1</sup>) and phenylmethylsulphonyl fluoride (0.02 µg ml<sup>-1</sup>). Receptor-bound radioligand was separated by centrifugation of the incubation mixture, and was washed in HEPES-KOH buffer containing BSA  $(10 \text{ mg ml}^{-1})$  and quantified in a  $\gamma$  spectrometer. The specific binding at each concentration was calculated by subtracting the nonspecific binding observed at high concentration of S-14  $(1 \times 10^{-7} \text{ M})$  from the total binding. To check the parallelism between inhibition curves of the two peptides, the residual variances of the two curves were tested for homogeneity by an f-test and the lines tested for parallelism by a t-test, both with the aid of the computer program of Faden and Rodbard<sup>2</sup>

cortex. Both S-14 and S-28 produced dose-dependent inhibition of radioligand binding over a concentration range of 10<sup>-1</sup> 10<sup>-7</sup> M. In each tissue, displacement curves obtained with the two peptides were parallel. The potency of S-28 relative to S-14 was calculated from the concentrations of the two peptides required to inhibit 125I-Tyr11-SRIF binding to the membrane receptors by 50%, as shown in Table 1. S-28 exhibited 3.2-fold greater affinity for binding to S-14 receptors in the pituitary, whereas in the hypothalamus and cortex, it exhibited three- and sixfold lower affinities respectively. To determine whether S-28 is converted to S-14 during incubation with the membrane receptors, we analysed the S-28-containing reaction mixtures at equilibrium by Sephadex G-25 (superfine) gel chromatography and radioimmunoassay for somatostatin using an antibody (R149)<sup>2</sup> reacting 100% with S-28 and S-14. In these conditions, >99% of the immunoreactivity emerging from the columns co-eluted with synthetic S-28, showing that S-28 is not converted to S-14 during incubation with membrane receptors.

These data suggest that the higher potency of S-28 for in vitro growth hormone inhibition is due to its greater affinity for binding to pituitary S-14 receptors, as the receptor-binding affinity of the peptide (Table 1) correlates well with its reported 3-14-fold higher potency for growth hormone suppression from cultured rat anterior pituitary cells11. Although S-14 is known to exert characteristic effects in the central nervous system14, the effects of S-28 on brain have not yet been characterized. Based on our brain receptor binding data, however, S-28 would be expected to show reduced S-14-like biological activity in brain. Because S-28 can be enzymatically cleaved to S-14 (ref. 19), and as breakdown of S-28 to the tetradecapeptide form could influence the comparison of the potency of \$-28 relative to \$-14, it was necessary to determine the extent of the conversion during our incubation studies. Our finding that S-28 remains intact in the experimental binding conditions indicates that this molecule possesses its own intrinsic receptor binding properties.

What is the physiological significance of S-28? The present data clearly suggest that it is not simply a superactive form of

Concentrations (IC50) of S-14 and S-28 required for 50% inhibition of  $^{125}\text{I-Tyr}^{11}\text{-SRIF}$  binding

	IC <sub>50</sub>	Relative potency

S-14. As S-28 (or equivalent immunoreactivity) is present in high concentrations in the hypothalamus (approximately one-third of the amount of S-14)<sup>20</sup> and seems to be released into the hypophysial portal circulation<sup>21</sup>, it (together with S-14) is likely to be a regulator of pituitary growth hormone secretion. Likewise, the predominance of the S-28 form of somatostatin in some areas of the intestine<sup>5</sup> suggests specific regulatory roles for this peptide in this organ. Whether the effects of S-28 are a manifestation of its interaction with S-14 receptors alone or whether there are specific S-28 receptors distinct from those of S-14 remains to be established. The reduced ability of S-28 to compete with 125 I-Tyr11-SRIF for binding to brain S-14 receptors observed here, together with the recent finding that S-28 competes better with a radioiodinated S-28 analogue (125I-[Leu<sup>8</sup>, D-Trp<sup>22</sup>, Tyr<sup>25</sup>]S-28) for binding to brain membranes<sup>22</sup> than does S-14, provide evidence for the existence of separate receptors for S-14 and S-28 at least in brain. In any case, our observation that S-28 exhibits receptor-binding activities distinct from those of S-14, the reported differences in the biological actions of the two peptides and the high concentrations of S-28 in some tissues suggest that this molecule not only serves as a precursor of S-14 but also possesses independent physiological functions.

Synthetic S-28 was provided by Drs R. Guillemin and D. Coy. We thank Mrs M. Correia for secretarial assistance. This work was supported by grants from the Canadian MRC (MA-6196 and MA-6832) and the USPHS (AM 21373).

## Soluble factor activation of human B lymphocytes

Richard J. Ford\*, Shashikant R. Mehta, Daisy Franzini, Richard Montagna†, Lawrence B. Lachman‡ & Abby L. Maizel

\* Department of Pathology, The University of Texas System Cancer Center, M. D. Anderson Hospital and Tumor Institute, 6723 Bertner Avenue, Houston, Texas 77030, USA † Associated Biomedic Systems, Buffalo, New York 14202, USA ‡ Duke University Medical Center, Department of Microbiology and Immunology, Box 3829, Durham, North Carolina 27710, USA

Medium conditioned by lectin (and/or antigen)-stimulated human peripheral blood lymphocytes has been shown to contain factors, termed interleukin 1 (IL-1) and interleukin 2 (IL-2)1. which augment and maintain human T-cell proliferation3respectively. Interleukin 2 (T-cell growth factor, TCGF) requires the presence of a macrophage, or its monokine product, IL-1, for its production by T cells<sup>7-9</sup>. It has been shown that multiple signals are required for stimulating both T- and B-cell proliferation<sup>8-10</sup> but the factors necessary for optimal B-cell mitogenesis have not been rigorously defined. As both B- and T-cell stimulatory agents are present in lectin-stimulated peripheral blood lymphocyte-conditioned media, we studied the effects of the interleukin factors on human B cells. Human peripheral blood B lymphocytes and pokeweed mitogen (PWM)-stimulated B-cell blasts were evaluated for their proliferative response to soluble growth factors, which were obtained from either lipopolysaccharide or phytohaemagglutinin (PHA)stimulated peripheral blood mononuclear cells. We show here that factors from lipopolysaccharide-stimulated conditioned medium were unable to stimulate initial B-cell proliferation. However, factors from PHA-stimulated conditioned medium stimulated <sup>3</sup>H-thymidine (TdR) incorporation in both B cells and lectin-activated T cells. This stimulation could be maintained for multiple re-exposures to the growth factors, which suggests that a soluble factor present in medium conditioned by lectin-stimulated peripheral blood mononuclear cells may modulate B-cell proliferation in a manner analogous to T-cell

Human interleukin 1 was purified from mononuclear cellconditioned media by diafiltration, ultrafiltration and isoelectric focusing (pH 6.8-7.2)11. This material was co-mitogenic for human thymocytes and human T cells at a concentration < 1 ng per 25 µl and could not support the continuous growth of cultured T cells<sup>12</sup>. Interleukin 2 preparations, containing both T- and B-cell growth factors (see below), were purified from peripheral blood lymphocyte-conditioned media by ammonium sulphate precipitation (50-75% precipitate), DEAE-Sepharose chromatography (0.07 M NaCl elution fraction) and Ultrogel filtration ( $\sim 25,000$ -molecular weight ( $M_r$ ) fraction). This material, at all stages of purification, was capable of stimulating <sup>3</sup>H-TdR incorporation in 7-day-old activated T cells and capable of maintaining long-term T-cell growth<sup>13</sup>.

Table 1 illustrates the ability of the soluble factors contained in interleukin preparations to stimulate B-cell <sup>3</sup>H-TdR incorporation in the presence of fetal calf serum (FCS). In experiment 1, B cells were purified from peripheral blood by negative selection; they were isolated from those cells remaining after a double adherence protocol and E-rosette depletion. These cells were ≥88% immunoglobulin-positive with the remaining cells composed of null cells, polymorphs and a small percentage of nonspecific esterase-positive cells. The B cells in experiment 2 were further purified by passage over a Sephadex G10 column<sup>14</sup>. These cells were >95% surface immunoglobulin-positive (SIg<sup>+</sup>) and contained less than 1% T cells as determined by reactivity to anti-Leu-1 monoclonal antibody. As expected, PWM stimulation of a quiescent B-cell population

Cells were cultured in microtitre plates in a final volume of 0.2 ml. Total numbers of B cells added were  $0.2 \times 10^6$ , T cells (where added) were  $0.2 \times 10^6$  and MØ were  $0.04 \times 10^6$  (where added). The cells were grown for 48-72 h then labelled with 1 µCi 3H-TdR for the final 24 h. Standard errors of the mean were routinely <7%. In experiment 1, the B cells were prepared from peripheral venous blood by negative selection. E rosette-positive cells were removed on Ficoll gradients and the nonspecific esterase-positive cells removed by several adherence steps on Petri After these procedures the cell population was 88% SIg+ by immunofluorescence and contained <1% E rosette-positive cells. In experiment 2, peripheral blood B lymphocytes purified as described for experiment 1 were further processed by passage over a G10-Sephadex column. After this step, the recovered population contained 95% SIg+ cells and <1% T cells, as determined by E-rosetting and using anti-Leu-1 monoclonal antibody specific for human T cells. ND, not determined.

\* PWM was used at a final dilution of 10 µl per ml culture volume (Gibco). T cells were prepared from peripheral venous blood from the nonadherent. E rosette-positive, nylon wool-fractionated population as previously described21 The T cells were irradiated (1,500-2,000 rad) before co-cultivation with the B cells. After irradiation these T cells failed to incorporate significant <sup>3</sup>H-TdR in response to lectin exposure.

† In this experiment, IL-1 was used at a 1:100 final dilution. Further experi-

ments using multiple dilutions gave the same results.

‡ The IL-2 preparation (containing both B- and T-cell stimulatory factors) was processed by selective ammonium sulphate precipitation followed by DEAE-Sepharose chromatography, and was used at a final dilution of 1:10. To confirm that residual contaminating T cells (unexposed to lectin) in the B-cell population would not respond to DEAE-chromatographed conditioned medium alone (that is, the IL-2 preparation was free of residual lectin), we tested the preparation on quiescent peripheral blood lymphocytes in comparison with long-term cultured polyclonally activated T cells. <sup>3</sup>H-TdR incorporation of long-term cultured lines, in the presence of multiple dilutions of IL-2, was 16,924 ± 2,537 c.p.m. at 1:4 dilution and 214 ± 29 at 1:128 dilution. This is in striking contrast to peripheral blood lymphocytes, which showed 3H-TdR incorporation of only 73 and 20 c.p.m. at 1:4 and 1:128 dilution, respectively.

§ The IL-2 preparation (containing both B- and T-cell stimulatory factors) was

processed as in experiment 1 but was further fractionated by gel filtration on a Ultrogel AcA54 column. That activity eluting at Mr 24,000 was tested in experi-

ment 2, at a final dilution of 1:20.

Table 2 Evaluation of T-cell component in mitogenic assay of B-cell proliferation

B cells + T cells $(0.002 \times 10^6)$ + IL-2	20,223

B and T cells (where added) were incubated in 0.2 ml in microtitre wells for 48 h, then 1 μCi 3H-TdR was added to each well. After 24 h the cells were collected as described in Table 1 legend. The IL-2 preparations were added as 10% (v/v) of the final culture medium.

These T cells were irradiated (2,000 rad) before co-cultivation.

† The IL-2 preparation was fractionated through DEAE-Sepharose as described in Table 1. This IL-2 (and that in Tables 3 and 4) contains both T- and B-cell stimulatory factors. The IL-2 preparation was shown to stimulate <sup>3</sup>H-TdR incorporation of the magnitude demonstrated above in isolated B-cell preparations from multiple donors including the results shown in Table 1.

‡ These T cells and those in the following groups were not irradiated before co-cultivation.

was augmented in the presence of irradiated (2,000 rad) T cells and macrophage  $M\emptyset$ . Testing of the interleukins revealed that IL-1 had no activity when added by itself to B cells. However, the IL-2 preparations, fractionated by either DEAE-Sepharose chromatography or DEAE-Sepharose plus Ultrogel chromatography, contained moieties that stimulated B-cell populations; these preparations showed a stimulation index equal to or greater than that seen in the same cells after PWM stimulation. To ensure that any potential residual T-cell contamination of the purified B-cell population was not responsible for the DNA synthesis seen in Table 1, increasing numbers of nylon wool-purified T cells were added to the purified B cells and then stimulated with the soluble factors contained in the IL-2 preparations fractionated through DEAE-Sepharose chromatography (Table 2). As quiescent, non-lectin-activated T cells should not be stimulated by the lectin-free IL-2 preparations alone<sup>15,16</sup>, we expected that the T cells would not account for the increased thymidine incorporation observed. The results (Table 2) show that addition of irradiated or non-irradiated T cells did not increase the level of <sup>3</sup>H-TdR incorporation by B cells in response to the soluble factors in the IL-2 preparations.

As IL-2 has been shown to support T-cell blast proliferation in vitro, we next evaluated whether the IL-2 preparations would have any activity on PWM-stimulated B-cell blasts. We prepared B-cell blasts by adding PWM and irradiated syngeneic T cells to the B-cell population and incubating the cells in 5% CO<sub>2</sub> for 72-96 h. The irradiated T cells were then rosetted with sheep red blood cells (SRBC) and removed on Ficoll-Hypaque gradients while the  $M\emptyset$  component was removed by adherence. The B-cell blast population was then stimulated with the IL-2 preparations containing B-cell growth factor for 72 h and <sup>3</sup>H-TdR incorporation was measured during the last 24 h. Table 3 shows that soluble factors within DEAE-Sepharose-fractionated IL-2 preparations stimulated significant <sup>3</sup>H-TdR incorporation. Serial studies in which the blasts were re-stimulated with the B-cell growth factors at 72-h intervals, revealed that thymidine incorporation could be maintained for multiple reseedings and could be accounted for by B-cell stimulation alone. If the growth factor was deleted during these sequential studies, proliferation ceased. Furthermore, the percentage of

Table 3 Effect of soluble factors in interleukin preparations on PWM-stimulated human B-cell blasts

Days in culture	Cells labelled	<sup>3</sup> H-TdR incorporation (c.p.m.)	% Contamination by T cells
(	B cells	1,586	0
7 {	B cells B cells + IL-2 (containing both T- and B-cell stimulatory factors)*	7,824	1
	B cells	1,693	0
11 {	B cells B cells + IL-2	51,672	2
14 {	B cells B cells + IL-2	1,336	0
14	B cells + IL-2	28,256	0

\* Purified B cells were mixed with an equal number of purified, irradiated (1,500 rad) T cells and 10% MØ by concentration. The cells were stimulated for 96 h with PWM (10  $\mu$ l ml $^{-1}$ ) at which time the cells were depleted of adherent cells and E-rosettable cells as described in the text. The repurified B-cell blasts were then cultured in tubes (Falcon 3033) either in medium + FCS, or medium + FCS + the IL-2 preparation (1:10). The blasts were seeded at  $5\times10^5$  cells ml $^{-1}$  and re-fed with either medium–FCS alone or medium–FCS and the IL-2 preparations (containing both B- and T-cell stimulatory factors) every 72 h in association with re-feeding at the original concentration. In all cases, the B blasts were re-fed every 72 h; 24 h before re-feeding, an aliquot was labelled with 1  $\mu$ Ci  $^3$ H-TdR and the acid-precipitable material collected on Whatman GF/C filters and counted. Results represent the mean c.p.m. per assay point for a single experiment, with replicate experiments indicating the same trend; s.e.m. of cell population, <15%.

 Table 4
 Effect of soluble factors in Ultrogel-fractionated interleukin-2 preparations on B cells

Dilution of	<sup>3</sup> H-TdR incorporation (c.p.m.)*								
IL-2	Quiescent B cells	B-cell blasts†							
attackers.	$705 \pm 86$	$2,438 \pm 421$							
0.1%	$606 \pm 53$	$3,116 \pm 1,001$							
0.5%	$3,047 \pm 943$	$16,067 \pm 854$							
1.0%	$3,340 \pm 418$	$7,455 \pm 2,983$							
5.0%	$16,670 \pm 4,868$	$18,465 \pm 1,402$							
10.0%	$9,639 \pm 3,326$	$18,602 \pm 862$							

The IL-2 preparation was purified by DEAE-Sepharose and Ultrogel chromatography. Active material eluting from the DEAE-Sepharose column was stabilized with polyethylene glycol  $^{13}$ . The active fraction was then placed on an Ultrogel AcA54 column and the peak of T-cell activity eluting in the  $\sim\!24,000\text{-}M_r$  range collected. This material (0.1% final volume) acting on lectin-stimulated T-cell blasts in a microtitre assay, gave 1,393 c.p.m.  $^3\text{H-TdR}$  incorporation at 72 h, whereas a 10.0% final volume gave 18,323 c.p.m. incorporated.

\* Cells were placed in microtitre wells as described in Table 1 legend except that, 24 h before collection, they were labelled with  $0.5~\mu Ci^3$ H-TdR.

† B-cell blasts were prepared by stimulating purified B cells for 24 h in the presence of PWM. At the time of the microtitre assay, the PWM was washed from the cells and the IL-2 preparation added as above.

E-rosettable cells did not increase with time (Table 3), which strongly argues against the possibility that either T cells or null cells developing T markers account for the proliferation observed.

The results in Table 4, together with the data of Table 1, experiment 2, further demonstrate the presence of B-cell stimulatory factors in those IL-2 preparations that have been fractionated further by Ultrogel chromatography<sup>13</sup>. This material has been shown to contain a minimum of four bands discernible by gel electrophoresis. The factor(s) present in this fraction were again able to support the incorporation of <sup>3</sup>H-TdR by purified B cells as well as purified T cells.

These data reinforce the concept that normal human B lymphocytes are auxotrophic, requiring accessory cell signals for activation<sup>17,18</sup>. Most human B-cell mitogens such as PWM and Staphylococcus Protein A have been shown to be predominantly T-cell dependent in man<sup>19,20</sup>. Various T-cell helper factors such as AEF<sup>21</sup>, LMF<sup>22</sup>, and T-cell replacing factor<sup>23</sup>, all require T cells for their production. Reinherz et al.<sup>24</sup> have shown that LMF is a product of a monoclonal antibody-defined T helper subset. Macrophages are also apparently involved in B-cell activation by facilitating the interaction with helper T cells<sup>25</sup>, and later by stimulating differentiation<sup>26</sup>. Our study suggests that the interleukins as presently purified belong to this family of T-cell helper factors and factors within the preparations will stimulate <sup>3</sup>H-TdR incorporation in both quiescent B cells as well as activated B-cell blasts in FCS.

The major question now is whether this proliferative response of B cells to the soluble factors in the interleukin 2 preparations is due to a nonspecific mitogenic effect of the putative T-cellspecific lymphokine or due to a co-purifying B-cell-specific growth factor. Experiments are being done to resolve this question by means of differential factor absorption from the IL-2 preparations. Initial observations indicate that when the IL-2 preparations are absorbed by a population of B cells and then mitogenically tested on lectin-activated T cells, the activity of the absorbed material is frequently more active than a preparation that has not been absorbed. The converse experiment, where the IL-2 preparations are absorbed by T cells and then tested on B cells, also reveals a frequent augmentation of the B-cell response compared with material that has not been absorbed (data not shown). Furthermore, absorption of the IL-2 preparations by B cells fails to remove T-cell-specific activity and T-cell absorption fails to remove the activity that acts on B cells. These preliminary studies suggest that either absorption leads to factor release in the media, or that the interleukin preparations contain co-purifying but separate B- and T-cellspecific stimulatory factors.

This work was supported in part by NIH grants CA21927 and CA25411. We thank Dr Barbara Ruppert for help with the B-cell preparations, Mary Betz for technical assistance and Catherine Johns and Cleo Krieg for preparing the manuscript. This work formed part of a thesis (S.R.M.).

## Tumour promoters induce mitotic aneuploidy in yeast

#### James M. Parry\*, Elizabeth M. Parry\* & J. Carl Barrett†

Tumour promoters, which complete the process of carcinogenesis initiated by subthreshold doses of carcinogens, can effect changes in gene regulation and cellular differentiation<sup>1</sup> Whether tumour promoters also induce genotypic changes is unclear. 12-O-tetradecanoylphorbol-13-acetate (TPA), potent tumour promoter, is inactive in gene mutation assays<sup>1-6</sup>, but has been reported by some<sup>6,7</sup>, though not others<sup>3-1,9</sup>, to induce sister chromatid exchanges, which may be cytological indications of recombinational events<sup>11</sup>, in mammalian cells. However, TPA alone is not recombinogenic in yeart<sup>12</sup>. We now report that in a genetic system using the yeast Saccharomyces cerevisiae 13-18, TPA fails to induce recombination but induces mitotic aneuploidy—a change in chromosome number which may lead to hembygodity of recessive mutations or to phenotypic changes due to an alteration in gene balance. The ability of other agents to induce aneuploidy in this system also correlates with their tumour-promoting activity.

The compounds studied were assayed for their abilities to induce mitotic an euploidy (see Fig. 1 for method) and crossing-over in the  $D_6$  strain of S. cerevislae <sup>13-15</sup>, a diploid strain that carries a series of recessive, coupled markers on chromosome VII. The compounds tested included several promoters and structurally related nonpromoters. All promoters tested for the ability to induce aneuploidy were positive, whereas nonpromoters were negative (Table 1). Figure 2 plots the dose-response curve for TPA induction of aneuploidy, showing that dose-related increases in mitotic aneuploidy were obtained over the concentration range 0.02-5 μg ml<sup>-1</sup>. Phorbol-12-13didecanoate (PDD), another potent promoter in the phorbol ester series16, was also positive (Table 1). In contrast, no significant increases in aneuploidy were observed with phorbol, phorbol monoesters, 4-O-methyl-TPA or  $4\alpha$ -PDD, which are also inactive as promoters on mouse skin<sup>16</sup>

Of particular interest is mezerein—a weak promoter, but as potent as TPA in inducing many biochemical and morphological effects in cells 15,17. In a two-stage promotion protocol on mouse skin<sup>17</sup>, mezerein is an incomplete promoter, that is, it is not effective in the first stage of promotion but is as effective as TPA in the second stage. In the concentration range 0.01-100 µg ml<sup>-1</sup>, mezerein did not induce mitotic aneuploidy in our RESERV

Other structurally unrelated promoters, including anthralin18, lodoacetic acid19, saccharin20, oleic acid21,22 and lauric acid22 did induce mitotic aneuploidy. Stearic acid, a nonpromoter22, was inactive. Diethylstilboestrol, which may be a tumour promoter as well as initiator23, was positive.

In contrast with the ability of the tumour promoters to induce mitotic aneuploidy, they had no effect on the frequencies of mitotic crossing-over. However, Fig. 3 shows that, in identical conditions, the incomplete promoter mezerein did induce mitotic crossing-over at concentrations >10 µg ml<sup>-1</sup> whereas TPA was ineffective. Mezerein was the only compound tested which showed significant activity in the crossing-over assays.

The expression of recessive mutations resulting from homozygosity produced by mitotic recombination has been suggested as an important step in tumour promotion. However, with the exception of the incomplete promoter mezerein, none of the compounds tested was capable of inducing detectable : levels of mitotic crossing-over in the yeast strain used here. In view of the relative ease with which mitotic crossing-over may be detected in yeast after treatment with complete carcinogens and initiating agents<sup>24</sup>, it seems unlikely that the tumour promoters tested are capable of producing significant levels of mitotic recombination. The potential significance of the ability of mezerein to induce mitotic crossing-over is not clear.

Boutwell<sup>25</sup> has proposed that the promotion phase of carcinogenesis consists of at least two parts: phase I involving 'conversion' of the initiated cell and phase II the 'propagation' of the converted, initiated cell<sup>25</sup>. Complete promoters, such as TPA, can induce both phases but some substances, such as mezerein, are incomplete promoters and can induce only the second phase<sup>17</sup>. Recently, Slaga and co-workers<sup>17</sup> confirmed this multi-stage model of tumour promotion and demonstrated that the conversion phase, like the initiation phase of carcinogenesis, requires only a single exposure to the cocarcinogen, although a dose-related increase occurs with additional exposures<sup>17</sup>. Furthermore, the conversion phase is irreversible, for at least 4 weeks after a single exposure to TPA (T. Slaga, personal communication). It is possible that the conversion phase of promotion requires a genetic change induced by the tumour promoter. The correlation of aneuploidy induction with promoters, nonpromoters and the incomplete promoter mezerein is consistent with a role for chromosome changes in this phase. The epigenetic changes induced by promoters in gene regulation and cellular differentiation are probably also important in overall tumour promotion.

We have shown an apparent correlation between the ability of a compound to induce mitotic aneuploidy in S. cerevisiae and its ability to act as a tumour promoter. While such a correlation may be coincidental, we suggest that it reflects a mechanistic relationship between chromosome aneuploidy and tumour promotion. Most chemical carcinogens have been shown to be capable of inducing point mutations in experimental systems? however no such activity has been demonstrated for tumour

Table 1 Correlation of tumour-promoting activity and induction of aneuploidy or crossing-over in assays using yeast strain D<sub>6</sub>

Concentrations are those tested and, in most cases, represent those over which cell viability of tested cells was > 10% of the control value. At high levels of cell lethality, the reliability of the assay was reduced. A positive response was a threefold or greater increase in the frequency of aneuploid colonies in at least two separate experiments. In the case of phorbol-13-acetate, a small (twofold) increase was observed but the results obtained were not significantly different from the control values. A negative response was indicated if no significant increase in the frequency of aneuploid colonies or mitotic crossing-over occurred in either the left or right arm of chromosome VII. In the case of compounds 1, 2, 3, 4, 5, 6, 7, 9 and 13, no increases have been observed in the frequencies of induced mitotic recombination (including both gene conversion and crossing-over) in a variety of strains of yeast. The table also illustrates the maximum frequency of both induced aneuploidy and crossing-over observed in a single experiment. All the experiments used yeast cultures alone without the presence of an extracellular activating system involving rat liver microsomes (S9 mix). In the case of 12-O-tetradecanoyl-13-acetate, S9 mix reduced the induced frequency of aneuploid cells. The level of aneuploid cells in the control cultures was  $3-9 \times 10^{-6}$  viable cells. Compounds were from: 1-6, Dr Peter Borchert (Chemical Carcinogenesis, Minnesota); 7, Consolidated Midland (New York); 9-13, Sigma; compound 8 was a gift from Dr Tom Slaga (Oak Ridge National Laboratory).

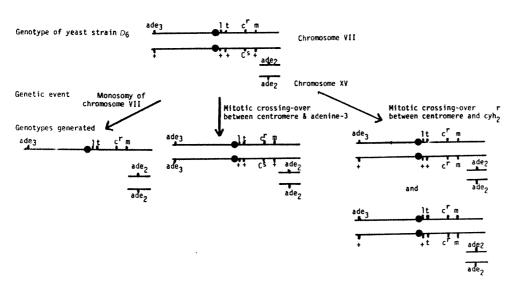

Fig. 1 Principles involved in the detection of mitotic aneuploidy in strain D6. Cells homozygous for the ade2 mutation require adenine for growth and produce red colonies; homozygosity of the ade3 mutation, which occurs at an earlier step in adenine synthesis, leads to the production of white, adenine-requiring colonies. Homozygosity of all the markers on chromosome VII may also result from simultaneous crossing-over in both the left and right arm of chromosome VII; however, such events are measurable by the frequency of crossing-over assayed in both arms separately. The possible role of such multiple cross-over types in the origin of white, cycloheximide-resistant colonies has been extensively discussed elsewhere 13. l, Leucine; t, tryptophan; c', cycloheximide resistance-2; methionine 13, C\* = cycloheximide sensitivity-2.

Phenotypes

white, cycloheximide resistant, requiring adenine, leucine, tryptophan and methionine

white, cycloheximide sensitive, requiring adenine

red, cycloheximide resistant, requiring adenine and methionine

promoters, which seem incapable of direct interaction with DNA. Our data support the hypothesis that tumour promoters act by stimulating the expression of recessive mutations (presumably in regulatory genes) produced by an initiating agent or by altering gene balance, both of which could result from changes in chromosome number as a result of chromosome aneuploidy. Such changes in chromosome number have frequently been observed in the karyotypes of tumour cells27 and the data reported here suggest they are causal in tumour

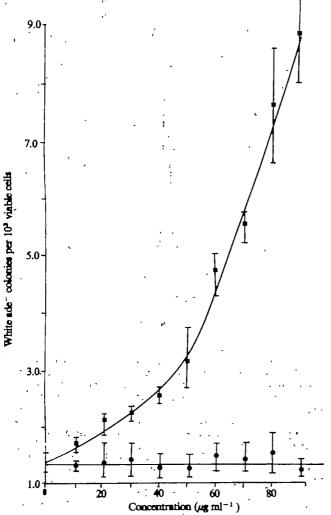

Fig. 2 Induction of mitotic anemploidy in cultures of yeast strain D<sub>4</sub> after exposure to TPA ( $\bullet$ ) or mezerein ( $\blacksquare$ ). Cultures of strain D<sub>4</sub> were collected during exponential growth, washed and resuspended in pH 7.0 phosphate buffer at a cell concentration of  $10^7$  ml $^{-1}$ . Cell samples (2 ml) was incubated at 30 °C in scaled bottles in a shaking water bath for 6 h in the presence of TPA or mezerein at concentrations of up to 5µg ml<sup>-1</sup> (both compounds were prepared as stock solutions in dimethyl sulphoxide). Complete growth medium (2 ml) was then added to each bottle, and staking and incubation continued for a further 18 h. In the experiment shown, 18 ml of growth medium were added. Cultures were washed three times by centrifugation, resuspended in sterile saline and plated after suitable dilution on year complete medium to score cell viability and on yeast complete medium plus of cycloheximide to score white, cycloheximide-resi monosomic (2n-1) colonies. All treated cultures were examined microscopically after washing and in no case was there evidence of sporulation amongst the diploid cells. Viability plates were scored after 5 days and the frequency of monosomic colonies after-10 days of incubation at 28 °C. Representative samples of white, cycloheximide-resistant colonies were replicated onto selective minimal plates to determine the expression of the recessive markers on chromosome VII of strain De. All compounds reported here as inducing mitotic aneuploidy gave rise to white, cycloheximide-resistant colonies requiring adenine, leucine, tryptophan and methionine, as would be expected of cells which have lost one copy of chromosome VII. Details of the genetic basis of this assay are described in ref. 14. It is technically possible that some homozygous colonies arose from melotic recombination during the treatment period; however, in none of the cultures sed recombination would have been moiosis observed and incres obsérvable in our crossing-over assay.

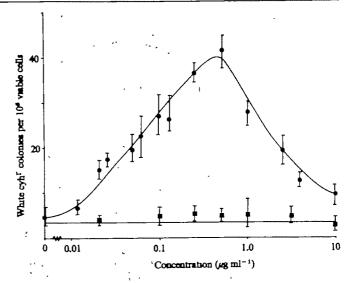

Fig. 3 Induction of mitotic crossing-over in cultures of yeast strain D<sub>6</sub> after exposure to TPA (\*\*) and mezerein (\*\*\*). Cultures were exposed to either compound at concentrations of up to 100 µg ml<sup>-1</sup> in the conditions described in Fig. 2 legend. After treatment, cultures were plated for cell viability, for the induction of white, cycloheximide-registrant, monoscomic colonies and for the frequency of white, cycloheximide-sensitive colonies produced on yeast complete growth medium at dilutions giving 10 times more viable cells than on the viability plates. All treated cultures were examined microscopically after washing and in no case was there any evidence of sporulation among the diploid cells. White, cyclohexumdesensitive colonies were replicated onto supplemented (with leucine, tryptophan and methionine) minimal plates. More than 90% of the white colonies are adenine requiring and result from mitotic crossing-over between the centromere and the edestre-3 gene on the left arm of chromosome VII. Assays of mitotic crossing-over were also performed using the cyclohextmide-2 gene on the right arm of chromosome VII with similar results.

development. The changes in chromosome aneuploidy would readily fit the multi-stage models of carcinogenesis.

The data presented here do not indicate whether the assay of induced chromosome aneuploidy in yeast will be useful in detecting tumour promoting chemicals. Such a conclusion awaits the demonstration that chromosome aneuploidy is also induced in mammalian cells by tumour promoters.

# Isolation of I-A subregion-like molecules from subhuman primates and man

#### Sanna M. Goyert\* & Jack Silver†

\* Department of Pathology, Irvinton House Institute, New York University, New York, New York 10016, USA † Department of Microbiology and Public Health, Michigan State University, East Lansing, Michigan 48824, USA

Immune response-associated (Ia) molecules play a major part in cellular interactions that initiate an immune response. Two families of Ia molecules, determined by the I-A and I-E subregions of the murine major histocompatibility complex (MHC), have been isolated and characterized in mice1. I-A and I-E molecules each consist of two polypeptide chains (molecular weights  $(M_rs)$  of 26,000 and 35,000 for I-A and 24,000 and 32,000 for I-E) that are noncovalently associated2. Their large subunits are designated  $A_{\alpha}$  and  $E_{\alpha}$ , respectively, and their small subunits  $A_{\beta}$  and  $E_{\beta}$ . Despite the similarity in their subunit composition, the I-A and I-E molecules are structurally distinct according to peptide mapping and partial N-terminal sequence analysis<sup>3,4</sup>. Although the structural homologue of murine I-E molecules has been identified in man and is known as HLA-DR5, the I-A equivalent has never been described. In an attempt to identify the human analogue of the murine I-A molecule, murine monoclonal antibodies were produced after immunization with a mixture of three putative human cell lines. We report here that one of these antibodies reacts with I-A-like molecules from two cell lines, GM3158, which after karyotype analysis was shown to have originated not from man but from a marmoset, and GM3163, a cell line of human origin.

Monoclonal antibodies to cell surface molecules were produced by immunizing BALB/c mice with a mixture of the cell lines GM3107, GM3158 and GM3163 (obtained from the Human Mutant Cell Repository, Camden, New Jersey) and fusing the immune splenocytes with SP2/O-Ag cells. After appropriate screening by indirect immunoprecipitation, several positive clones were identified—two of these, designated SG157 and SG171, were analysed further. When tested with a lentil lectin-purified glycoprotein fraction from cell line GM3158, the monoclonal antibodies precipitated molecules having two, slightly different profiles after SDS-polyacrylamide gel electrophoresis (PAGE) (Fig. 1). SG157 precipitated products with SDS-PAGE profiles characteristic of human HLA-DR antigens: two polypeptides of Mrs ~29,000 and 34,000, respectively with the smaller subunit  $(\beta)$  displaying the characteristic retardation in migration rate in reducing conditions<sup>2</sup>. In contrast, SG171 precipitated two molecules of different molecular weights (~30,000 and 33,000); in reducing conditions these merge into a single peak with an apparent  $M_r$  of 33,000. Peptide map comparisons (Fig. 2) of the molecules isolated with SG157 and SG171 reveal striking differences which suggest that, despite similarities in their molecular weights, the molecules detected by SG157 and SG171 are unrelated.

The molecules binding to SG157 and SG171 were identified by limited amino acid sequence analysis (Table 1). The two polypeptide chains reacting with SG157 show a high degree of sequence identity, 9 of 11 residues (82%), with the two polypeptide chains of the murine I–E molecule and thus represent the marmoset analogue. In contrast, the two polypeptide chains reacting with SG171 are homologous to the murine I–A molecule. The large ( $\alpha$ ) subunit of the molecule binding to SG171 is identical to a prototype of the large subunit of murine I–A molecules ( $A_{\alpha}$ ) in 5 of 8 sequence residues that can be compared, provided a gap is inserted at the amino terminus.

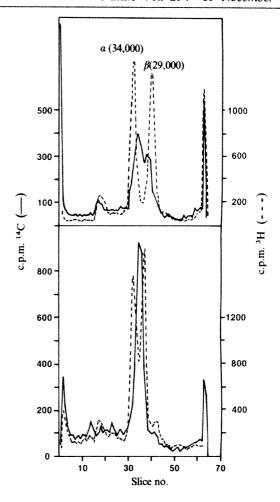

Fig. 1 SDS-PAGE profiles of molecules isolated from cell line GM3158 with SG157 (---) and SG171 (- monoclonal antibodies in non-reducing (top) and reducing (bottom) conditions. Cells  $(2 \times 10^8)$  were labelled in culture with either <sup>3</sup>H- or phenylalanine and their glycoprotein components were isolated as described elsewhere8. The relevant molecules were isolated by adsorption of the radiolabelled glycoprotein fractions on to an immunoadsorbent column consisting of monoclonal antibody (SG157 or SG171) covalently coupled to Sepharose-4B, followed by elution with 0.05 M diethylamine. The eluted material was lyophilized, dissolved in water and acetone precipitated. The precipitates were dissolved in Laemmli<sup>14</sup> non-reducing sample buffer and <sup>14</sup>C- and <sup>3</sup>H-labelled material was mixed in a 2:1 ratio. One half of the sample was reduced with 2-mercaptoethanol. The samples were electrophoresed on 12.5% polyacrylamide gels and the gels were sliced into 1 mm thick sections. After overnight incubation in water the entire slice, as well as the eluted material, was counted in a liquid scintillation counter. Radioactivity (c.p.m.) was corrected for <sup>3</sup>H and <sup>14</sup>C channel spillover.

Furthermore, the small subunit  $(\beta)$  is identical to that of the murine I-A molecule  $(A_{\beta})$  in 6 of 7 sequence residues that can be compared. The combined degree of homology, 11 of 15 residues (73%), is comparable with that observed between other MHC products of different species (that is, mouse and man)<sup>5,6</sup>, and strongly suggests that the molecule reacting with SG171 is the homologue of the murine I-A molecule.

The marmoset I-A molecule differs in several respects from its murine counterpart. Although both consist of two noncovalently associated subunits of similar molecular weight, the two subunits of the murine I-A molecule are generally better resolved on SDS-polyacrylamide gels<sup>2</sup>. In addition, whereas reducing conditions do not appreciably alter the migration rate of either subunit of murine I-A molecules compared with those of the unreduced forms when analysed by SDS-PAGE, the small

Cells were radiolabelled in vitro with several <sup>3</sup>H-amino acids and SG157 and SG171 molecules were isolated and purified as described in Fig. 1 legend. Proteins were sequenced and residues identified as described elsewhere. Boxed residues represent identities between species and dashes indicate presence of residue found in one species but absent from the other. The murine sequence data were compiled from refs 3, 5, 12 and 13.

subunits of marmoset I-A- and I-E-like molecules migrate more rapidly in non-reducing conditions. Furthermore, one must insert a gap at the N-terminus of the large subunit of the marmoset I-A-like molecule to align it with the large subunit of the murine I-A molecule. A similar requirement applies to the I-E(DR)-like molecule, for which a gap must be inserted at the N-terminus of the small subunit to align it with the small subunit of the murine I-E molecule<sup>7</sup>. The significance, if any, of these similarities between I-A and I-E-like molecules in marmosets is unknown.

The recognition that GM3158 is a marmoset cell line explains our previous observation that the  $DR_{\alpha}$  chain isolated from GM3158 differs structurally from the  $DR_{\alpha}$  chains isolated from two human cell lines, GM3107 and GM3163 (ref. 8). Although the  $DR_{\alpha}$  subunit is essentially invariant in structure within a species (mouse or man)<sup>9-11</sup>, its structure obviously varies between species.

Identification of an I-A-like molecule in subhuman primates strongly suggests that this molecule also exists in man. Indeed,

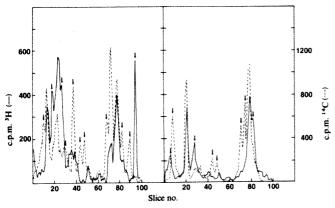

Fig. 2 Tryptic peptide comparisons of  $\alpha$  (left) and  $\beta$  (right) polypeptides isolated from GM3158 with monoclonal antibodies SG157 (---) and SG171 (----).  $^3$ H- and  $^{14}$ C-phenylalanine-labelled molecules were isolated with SG171 and SG157, respectively, and the component  $\alpha$  and  $\beta$  subunits separated by SDS-PAGE as described in Fig. 1 legend. Equivalent c.p.m. of  $^{14}$ C ( $\alpha$  or  $\beta$ )- and  $^3$ H ( $\alpha$  or  $\beta$ )-polypeptides were combined. After complete reduction, alkylation and trypsin-TPCK (tosyl-phenylethyl-chloromethyl-ketone) digestion, the peptides were separated on isoelectrofocusing gels as described elsewhere  $^8$ . The gels were sliced into 1-mm sections, incubated in water overnight and measured for radioactivity, which was plotted against slice number after correcting for  $^3$ H and  $^{14}$ C channel spillover. Arrows denote peptide differences.

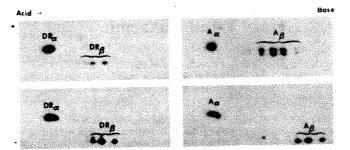

Fig. 3 Two-dimensional gel electrophoresis of DR- and I-A-like molecules isolated from cell lines GM3158 and GM3163. The DR- and I-A-like molecules were purified by immunoadsorption as described in Fig. 1 legend, except that Triton X-100 instead of deoxycholate was used in the elution step. The glycoprotein extract from GM3163 was first depleted of SG157-reactive material before being combined with the SG171 immunoadsorbent. The isolated material was analysed as described elsewhere  $^{15}$  except that non-reducing conditions were used throughout. The DR- and I-A-like molecules isolated from marmoset (top row) and man (bottom row) are distinguishable primarily by the difference in isoelectric points of the DR $_{\beta}$  and A $_{\beta}$  polypeptides. The marmoset and human I-A-like molecules have  $\sim\!90\%$  amino acid sequence homology (to be published).

preliminary results indicate that SG171 also reacts with an I-A-like molecule from some human cell lines. Two-dimensional gel analysis of molecules isolated from cell line GM3163 (confirmed by karyotype analysis to be of human origin) with SG157 and SG171 revealed DR- and I-A-like molecules respectively (Fig. 3). As in the marmoset, the  $A_{\beta}$  polypeptide is more basic than the DR\_{\beta} polypeptide. However, in contrast to the marmoset, human DR- and I-A-like molecules have almost identical molecular weights. It is also intriguing to note that the  $A_{\alpha}$  and DR\_{\alpha} subunits have not only identical molecular weights but also isoelectric points, suggesting that despite a lack of similarity in their NH\_2-terminal amino acid sequences, they may be evolutionarily related.

The similarity in molecular weights of the DR- and I-A-like molecules in man may explain why others have failed to identify the latter. It is likely that I-A-like molecules have been isolated but mistakenly identified as DR because of their similar migration rates when analysed by SDS-PAGE.

# Isolation of a new type C retrovirus (HTLV) in primary uncultured cells of a patient with Sézary T-cell leukaemia

Bernard J. Poiesz, Francis W. Ruscetti, Marvin S. Reitz, V. S. Kalyanaraman & Robert C. Gallo

Laboratory of Tumor Cell Biology, National Cancer Institute, National Institutes of Health, Bethesda, Maryland 20205, USA

Retroviruses have been isolated from many animal species and several have been shown to be the aetiological agents of naturally occurring leukaemias, lymphomas and sarcomas (for recent reviews see ref. 1). There is evidence that these viruses or components of them are present in humans, but the isolation and analysis of retroviruses from human cells and evidence for an association with disease have been difficult to demonstrate (see refs 2, 3). We now report the isolation and characterization of a new type C retrovirus (HTLV<sub>MB</sub>) from a patient with a cutaneous T-cell leukaemia (Sézary syndrome). Analysis of the proteins and nucleic acids of this retrovirus isolate indicates that it is closely related to HTLV<sub>CR</sub>, a retrovirus recently isolated and characterized<sup>5-7</sup> from a patient with cutaneous T-cell lymphoma (mycosis fungoides) but distinct from known animal retroviruses. Proteins and nucleic acids of HTLV were also identified in the fresh (uncultured) Sézary leukaemic blood cells from which the second isolate was derived.

Retrovirus particles are usually not demonstrable until cells are successfully grown in culture. As T cells are often target cells for transformation by type C retroviruses, it is necessary to grow human T cells in continuous culture to determine whether they contain these viruses. The discovery of T-cell growth factor (TCGF)<sup>8,9</sup> and its recent purification from human lymphocyte conditioned media 10 have now made it possible routinely to grow normal T cells for long periods if the TCGF is added periodically to lectin- or antigen-activated lymphocytes. Neoplastic cells can be separated and grown in culture without normal T cells by using purified TCGF because many neoplastic T cells differ from normal T cells in not requiring in vitro activation by lectin to interact with TCGF<sup>11</sup>. Some cultured neoplastic T cells become independent of exogenous TCGF<sup>11,12</sup> probably because they become constitutive TCGF producers<sup>13</sup>. The use of TCGF has thus enabled neoplastic cell lines to be established and their retrovirus-producing properties analysed.

Mycosis fungoides and Sézary syndrome are two distinct clinical variants of a group of neoplastic diseases referred to as

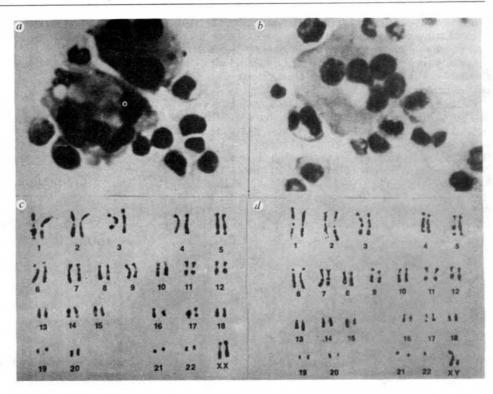

cutaneous T-cell lymphomas and leukaemias respectively14. The detailed clinical history of patient C.R. with mycosis fungoides has been published elsewhere<sup>4</sup>. The cell line, HUT102, was established from neoplastic T cells derived from his right inguinal lymph node<sup>12</sup>, using crude TCGF<sup>8</sup>. One year later, the cell line CTCL-3 was established from his peripheral blood using a lectin-free partially purified TCGF<sup>11</sup>. Patient M.B. was a 64-yr old black female with the leukaemic phase of Sézary syndrome. Examination of her peripheral blood revealed a white blood cell count of 300,000 mm<sup>-3</sup> with a differential of 72% lymphocytes, 35% of which had markedly convoluted nuclei, characteristic of Sézary leukaemic cells. The cell line CTCL-2 was established<sup>11</sup>, again using partially purified TCGF<sup>10</sup>, from a sample of her peripheral blood.

The characteristics of the three cell lines are similar and have been published in detail previously<sup>11,12</sup>. HUT102 and CTCL-2 are now grown independently of exogenous TCGF, while CTCL-3 remains dependent on its addition. Their morphology is that of atypical mono- and multi-nucleated lymphoblasts (Fig. 1a,b). Typical of T lymphoblasts, they form rosettes with sheep erythrocytes and are negative for Epstein-Barr virus nuclear antigen. Their histochemical staining pattern (negative for myeloid stains but positive for  $\alpha$ -naphthyl acetate esterase and acid phosphatase) and lack of terminal transferase activity are compatible with published reports on fresh cells from their disease of origin. Karyotypes performed on the cultured cells (Fig. 1c,d) are the same as those performed on the original fresh tissue source and have remained constant throughout culture (2 yr).

HUT102 and CTCL-3 are now constitutive producers of type C retrovirus particles (HTLV<sub>CR</sub>), while fresh peripheral blood lymphocytes from patient C.R. produced particles only after induction with 5-iodo-2'-deoxyuridine (IUdR). Similarly, CTCL-2 cells have produced typical type C particles (Fig. 2) from the earliest passage studied (passage 2), but only after induction with IUdR. Figure 3 summarizes the isolations of these viruses. As the cell lines are relatively poor producers of virus, large amounts of cells must be cultured for analytical studies. Typically, 20-501 of cells (10<sup>6</sup> per ml) are grown in RPMI-1640 with 10% fetal calf serum, and in the case of CTCL-2, the cells are also treated with IUdR (20 µg ml<sup>-1</sup>) for 24 h. The virus-releasing cells are then centrifuged, resuspended in fresh media and the media collected 72 h later. Virus particles are concentrated and purified by sequential banding in sucrose, pelleting through 30% glycerol and finally isopycnic banding in a continuous sucrose gradient. The fractions containing HTLV<sub>MB</sub> particles are identified by electron microscopy and by assaying for viral reverse transcriptase. These methods have been previously described for HTLV<sub>CR</sub> (ref. 4). As with  $\rm HTLV_{CR}$  and most other retroviruses, concentrated  $\rm HTLV_{MB}$  particles band at a density of 1.16 g ml<sup>-1</sup> and are associated with an endogenous DNA polymerase activity. The polymerase shows a preference for the synthetic template primers  $poly(A) \cdot oligo(dT) \quad and \quad poly(C) \cdot oligo(dG) \quad over \quad poly(dA) \cdot$ oligo(dT), characteristic of viral reverse transcriptase<sup>15</sup>. Like  $\rm HTLV_{CR}$  reverse transcriptase<sup>6</sup>,  $\rm HTLV_{MB}$  reverse transcriptase has a preference for  $\rm Mg^{2+}$  with  $\rm poly(A) \cdot oligo(dT)$  and poly(C)·oligo(dG) (data not shown).

Analysis of isolated core structures from HTLV<sub>CR</sub> has shown that a 24,000 molecular weight protein (p24) is a major component of the viral cores<sup>7</sup>; this protein has been purified<sup>7</sup>. In a competitive radioimmunoassay using labelled, purified  $HTLV_{CR}$  p24 and an antibody against whole disrupted HTLV<sub>CR</sub>, all known animal retroviruses tested to date have failed to compete, whereas purified HTLV<sub>CR</sub> and cells producing HTLV<sub>CR</sub> do compete<sup>7</sup>. Both HTLV<sub>MB</sub> and HTLV<sub>CR</sub> isolates competed in the HTLV<sub>CR</sub> p24 assay (Fig. 4a), suggesting a high degree of relatedness between p24 of the two isolates. Furthermore, cell lysates of cultured, IUdR-induced CTCL-2 T lymphoblasts also compete whereas lysates of normal phytohaemagglutinin (PHA)-stimulated human T lymphoblasts do not (Fig. 4a, b). These findings indicate that p24 is expressed in

Fig. 1 Morphology and karyotypes of CTCL-2 and HUT102 cells. Light microscopic appearance of cultured HUT102 (a) and (b) CTCL-2 cells. Cells were pelleted in a cytocentrifuge and stained with Wright-Giemsa. Both cell lines are morphologically similar, with atypical mono- and multinucleated lymphoblasts. Karyotype analysis was performed as previously described<sup>11</sup>. CTCL-2 metaphases (c) were those of a normal diploid human female (46, XX), while HUT102 metaphases (d) were predominantly those of a pseudodiploid human male (46, XY, minus chromosome 22, plus a minute).

CTCL-2 cells after IUdR induction but not in normal human T lymphoblasts with or without IUdR induction.

Liquid molecular hybridization experiments<sup>5</sup> on HTLV<sub>CR</sub> showed that: (1) HTLV<sub>CR</sub>  $^3$ H-cDNA hybridized almost completely (90%) to its own 70S RNA with kinetics consistent with the genetic complexity of other retroviruses, (2) HTLV<sub>CR</sub> was not significantly related to a wide variety of animal retroviruses (types B, C and D), including bovine leukaemia virus (BLV) and previously described endogenous and horizontally transmitted viruses from non-human primates, and (3) nucleic acid sequences related to  $^3$ H-cDNA or  $^{125}$ I-70S RNA HTLV<sub>CR</sub> were not found in DNA from several normal human tissues.

In liquid hybridization experiments to assess the nucleotide sequence relatedness of HTLV<sub>CR</sub> and HTLV<sub>MB</sub>, 90% of the <sup>3</sup>H-cDNA from HTLV<sub>CR</sub> hybridized to HTLV<sub>CR</sub> 70S RNA and 54% to RNA from cultured HUT102 cells. In contrast, there was no significant hybridization (<10%) to RNA from phytohaemagglutinin (PHA)-stimulated human peripheral blood T lymphocytes from 20 pooled normal donors, to RNA from a normal human embryonic cells line, or to 70S RNA from several other type-C viruses (Table 1). As with cytoplasmic RNA of HTLV<sub>CR</sub>-producing cells, <sup>3</sup>H-cDNA prepared from HTLV<sub>CR</sub> also hybridized to IUdR induced CTCL-2 cytoplasmic RNA (45%). The kinetics of hybridization indicate that CTCL-2 cytoplasmic RNA contains about 0.5% HTLV-specific sequences by weight (Fig. 5). The T<sub>m</sub>s of the resultant hybrids are identical with both sets of cell RNA (Fig. 5 inset).

 $^3\text{H-cDNA}$  from purified HTLV<sub>MB</sub> hybridized 43% to HTLV<sub>CR</sub> 70S RNA but only 19% to 70S RNA from avian myeloblastosis virus (AMV), providing further evidence that HTLV<sub>MB</sub> is closely related to HTLV<sub>CR</sub>. (The 19% value with AMV 70S RNA is indicative of a high background with this cDNA, not a specific relatedness to AMV.) As we had insufficient HTLV<sub>MB</sub> to prepare 70S RNA, we cannot say whether 43% represents the maximum ability of this cDNA to hybridize to the 70S RNA of HTLV<sub>CR</sub> or whether the HTLV<sub>MB</sub> and HTLV<sub>CR</sub> have some nonprelated sequences. The data clearly show, however, that the two isolates are at least closely related. This relationship is now being investigated further.

A frozen portion of the original (uncultured) neoplastic peripheral blood cells used to establish cell line CTCL-2 from patient M.B. was examined for the presence of HTLV<sub>CR</sub>-related

proteins and nucleic acid sequences. Proteins from cell lysates of these fresh cells competed effectively in the radioimmunoassay for HTLV<sub>CR</sub> p24, whereas extracts from PHA-stimulated normal human T lymphoblasts did not (Fig. 4b). Cell proteins were fractionated by phosphocellulose column chromatography as described elsewhere and the fractions eluting from a NaCl gradient at 150–300 mM were positive for HTLV p24 as assessed by competition with  $^{125}\text{I-p24}$  of HTLV in competition radioimmunoassays (Fig. 4b). These results indicate that a protein antigenically related or identical to HTLV<sub>CR</sub> p24 was

HTLV  $^3$ H-cDNA (500–1,000 c.p.m.) was hybridized to 1  $\mu$ g 70S viral RNA, 200–300  $\mu$ g cellular cytoplasmic RNA or 600  $\mu$ g cellular DNA as described previously  $^4$ - $^{20}$ , and the per cent hybridization determined by S<sub>1</sub> nuclease digestion. The values indicated are maximum plateau values in the conditions used. The heterologous viral 70S RNAs tested included those from gibbon ape leukaemia virus, Hall's Island strain (GALV $_{\rm H}$ ) $^{22}$ , baboon endogenous virus (BaEV) and avian myeloblastosis virus (AMV). The cell lines HUT102 and CTCL-2 are the abnormal T-lymphoblast cell lines derived from patients C.R. and M.B., respectively. The viruses produced by these two cell lines are shown in parentheses. PHA-stimulated lymphoblasts are human peripheral blood leukocytes pooled from 20 normal donors and stimulated in short-term culture (72 h) with PHA prepared as previously described<sup>23</sup>

<sup>\*</sup> Mean of 30 samples = 8%, s.d. = 4%.

present in the original uncultured tumour cells. The IUdR-induced cultured CTCL-2 cell lysates competed at a lower protein input (Fig. 4a) than the fresh lysate (50% competition for cultured cell lysate at 0.8  $\mu$ g protein compared with 150  $\mu$ g for the fresh cells), indicating a higher p24 concentration in cultured cells.

 $\rm HTLV_{CR}$   $^3\rm H\text{-}cDNA$  hybridizes to DNA from both cultured  $\rm HUT102$  (45%) and CTCL-2 (21%) cells, but not to DNA from normal human tissues nor to DNA from a human embryonal carcinoma cell line (Table 1). In addition,  $\rm HTLV_{CR}$  cDNA hybridized 17% to DNA from the original fresh peripheral blood neoplastic T cells of patient M.B. (Table 1), whereas hybridization of  $\rm HTLV$   $^3\rm H\text{-}cDNA$  to DNA of normal human tissues was 3–11% (>30 samples tested), mean  $8\pm4$  s.d. The differences between the degree of hybridization of  $\rm HTLV_{CR}$  cDNA to DNA of cultured cells from patient C.R. and DNA of

Fig. 3 Schematic representation of HTLV isolation from the fresh and cultured cells from two patients (C.R. and M.B.) with cutaneous T-cell lymphoma and leukaemia, respectively. The dots indicate that the cell lines continue to produce virus in succeeding culture passages. The p numbers refer to different passages of the cells in culture. IUdR refers to requirement of the cells for treatment with IUdR for release of HTLV, while 'constitutive' indicates that the cells either subsequently or originally produced HTLV without IUdR (see text for further details).

fresh and cultured cells from patient M.B. again suggest that some non-related nucleic acid sequences exist in the HTLV isolates. The specificity of this hybridization is emphasized by the fact that <sup>3</sup>H-cDNA from Simian Sarcoma virus, baboon endogenous virus, BLV, Rauscher murine leukaemia virus, squirrel monkey virus and langur endogenous virus failed to hybridize to CTCL-2 cytoplasmic RNA (data not shown). The hybridization of HTLV<sub>CR</sub> cDNA to DNA from the fresh Sézary T cells was significantly less than with DNA from cell lines

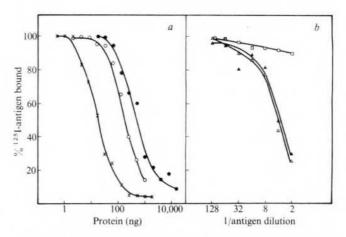

Fig. 4 Relatedness between p24 from HTLV<sub>CR</sub> and from HTLV<sub>MB</sub> and evidence for this p24 in fresh blood cells of patient M.B. HTLV p24 was purified by a combination of phosphocellulose chromatography and gel filtration in Biogel p60 as described earlier<sup>7</sup>. The proteins were iodinated by the chloramine-T method. The radioimmunoassays used 7,000 c.p.m. of <sup>125</sup>I-labelled HTLV p24 and a limiting dilution of a rabbit antibody to HTLV<sup>7</sup>. The viruses and cells used in the assays were solubilized in buffer containing 10 mM phosphate pH 7.5, 0.8 M NaCl, 0.5% Triton X-100 and 0.5 mM phenyl methyl sulphonyl fluoride. The competing unlabelled antigens used in the assay are: (in panel a) ×, HTLV<sub>CR</sub>; ○, HTLV<sub>MB</sub> from cultured CTCL-2 cells; ♠, extracts from cultured CTCL-2 cells; and (in panel b) △, fresh blood cells of patient M.B.; ♠, pool of the proteins from fresh blood cells of patient M.B. partially purified by phosphocellulose chromatography; □, extracts from cultured normal human T cells.

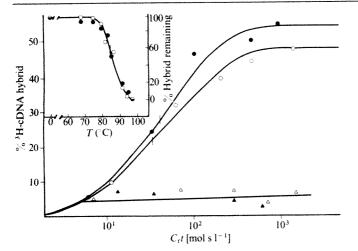

Fig. 5 Nucleic acid relatedness of HTLV<sub>MB</sub> to HTLV<sub>CR</sub>. HTLV<sub>CR</sub>  $^3$ H-cDNA was prepared as previously described $^5$ , hybridized to 200  $\mu g$  of the indicated cytoplasmic RNA in 50% formamide-3X SSC (1X SSC = 0.15 M NaCl, 0.015 M Na citrate, pH 7) with 0.05% SDS and 1 mM diethylpyrocarbonate, and the amoun of hybrid assayed by S<sub>1</sub> nuclease digestion. The cDNA was hybridized to the indicated  $C_r t$ . Values were normalized to the maximum value with HTLV 70S RNA (actual value 90%). Inset: cDNA was hybridized to a C,1 of 500, diluted 20-fold with 2X SSC, and incubated at the indicated temperature for 5 min. Hybridization is normalized to 100% for each hybrid (actual values 48% and 44%, respectively). •, HUT102 cytoplasmic RNA; ○, IUdR-treated CTCL-2 cytoplasmic RNA; △, human embryonic cell line cytoplsmic RNA; A, PHA-stimulated normal human blood T lymphoblasts obtained as previously described<sup>23</sup>.

infected by and producing HTLV. These findings are consistent with the presence of HTLV proviral sequences in DNA of a fraction of the primary tumour cells and/or the presence of only fractions of the provirus in most tumour cells.

Thus, the present data indicate that an isolate of a type C retrovirus (HTLV<sub>MB</sub>) from the cultured leukaemic cells of a patient with Sézary syndrome is closely related to HTLV<sub>CR</sub> from a patient with T-cell lymphoma, by virtue of their structural protein and nucleic acid sequence homology. Further studies are required to identify any differences between the two isolates. The observations that the HTLV isolates are not ubiquitous genetically transmitted viruses of man<sup>5</sup>, that HTLV-related nucleic acid sequences and proteins are found in fresh leukaemic blood cells of patient M.B. and that specific antibodies to HTLV occur in some human sera<sup>16.17</sup> indicate that HTLV has infected some humans. The results also suggest that its provirus was integrated into the human genome of at least some of the leukaemic cells. Consistent with these findings, recent electron microscopic studies of van der Loo et al. show apparent retrovirus-like particles in primary (uncultured) tumour cells of a patient with cutaneous T-cell lymphoma<sup>18</sup>

Many animal retroviruses are known to cause leukaemias and lymphomas of T cells in their host 19. Particularly interestingly, a cutaneous lymphoma can occur in sheep after inoculation with BLV<sup>20,21</sup>. HTLV has so far been found only in the neoplastic tissue of three patients with T-cell malignancies. Seroepidemiological studies and surveys of cell nucleic acids for HTLV sequences are in progress to obtain further evidence for a possible relationship of HTLV particles to these diseases.

We thank Dr C. Julian Rosenthal (SUNY Downstate Medical Center) for clinical history and tissue samples from patient M.B., Dr B. Kramarsky (Electronucleonics) for the electron micrographs, and A. Woods, D. McCartney, D. Kerr, M. Jarvis and M. Voltin for technical assistance.

# Antibodies in human sera reactive against an internal structural protein of human T-cell lymphoma virus

V. S. Kalyanaraman\*, M. G. Sarngadharan†, P. A. Bunn‡, J. D. Minna‡ & R. C. Gallo†§

\* Department of Cell Biology, Litton Bionetics Inc., 5516 Nicholson Lane, Kensington, Maryland 20895, USA † Laboratory of Tumor Cell Biology, National Cancer Institute,

Bethesda, Maryland 20205, USA ‡ Veteran's Administration Oncology Branch, National Cancer Institute, Bethesda, Maryland 20205, USA

Although retroviruses (RNA tumour viruses) have been implicated in the causation of naturally occurring leukaemias and lymphomas of animals1, it is not yet clear whether they are involved in the human versions of these malignant diseases, particularly because of the difficulty in isolating viruses truly ascribable to human origin<sup>2,3</sup>. However, a novel type C retrovirus (called  $HTLV_{CR}$ ) has been isolated in our laboratory from T cells (fresh and in culture) from a lymph node biopsy of a patient (C.R.) with cutaneous T-cell lymphoma (mycosis fungoides)4 and a very similar virus (HTLV<sub>MB</sub>) from the peripheral blood T cells of another patient (M.B.) with cutaneous T-cell leukaemia (Sézary syndrome, see accompanying report<sup>5</sup>). The nucleic acid sequence<sup>6</sup>, the reverse transcriptase and the major internal structural protein (p24) of HTLV<sub>CR</sub> are not significantly related to any of the known retroviruses; nucleic acid sequences and p24 protein of HTLV<sub>MB</sub> have been recognized in fresh and cultured cells<sup>5</sup>. We now describe the results of a limited survey of the occurrence, in patients with T-cell malignancies (and among normal people), of antibodies against HTLV<sub>CR</sub> proteins. We find that antibodies against p24 are present in human sera (including those of patient C.R. and his wife), and that these are specifically directed at HTLV<sub>CR</sub> proteins and not at cell-specific determinants—in other words, the immunological reactions are not those reported in human sera<sup>9-11</sup> against animal virus glycoproteins which, lacking virus specificity, are directed against the carbohydrate residues of the glycoprotein<sup>12,13</sup>. The antibodies against HTLV are thus the first evidence for a specific immune response in humans against a retrovirus.

A limited survey was designed to determine whether natural antibodies reactive against the human retrovirus isolate, HTLV, can be detected in human sera. The assay used in this preliminary survey was a radioimmune precipitation of 125I-labelled HTLV<sub>CR</sub> p24 by human sera using a double antibody system<sup>8</sup>. The p24 of HTLV<sub>CR</sub> was purified to homogeneity from density-

Competition radioimmunoassay (RIA) was performed as described in Fig. 2 legend using the competing viruses at 10 µg protein. Buffer 1 was used in the precipitations of <sup>125</sup>I-labelled HTLV<sub>CR</sub> p24 and buffer B in the precipitations of <sup>125</sup>I-labelled R-MuLV gp70. FeLV, feline leukaemia virus, SSV, simian sarcoma virus, BaEV, baboon endogenous virus; MPMV, Mason-Pfizer monkey virus; SMRV, squirrel monkey retrovirus; BLV, bovine leukaemia virus.

banded virus and radiolabelled with  $^{125}I$  as described elsewhere<sup>8</sup>. The serum from patient C.R. precipitated >90% of the labelled p24, and the serum of another patient (M.J.) with Sézary syndrome showed a similar high reactivity towards HTLV<sub>CR</sub> p24. Twenty-one other serum samples from various T-cell malignancies and 50 sera from random normal donors showed no significant precipitating activity. Sera were also obtained from 11 close family members of patients with T-cell malignancies, with previous evidence of HTLV infection. Out of these, one serum (no. 81-5, from the wife of patient C.R.) reacted strongly in the immunoprecipitation.

The reactivity of the positive sera was characterized in detail, and Fig. 1 shows the pattern of precipitation obtained. The radiolabelled probe used was 95% immunoprecipitable with a hyperimmune rabbit serum against disrupted HTLV<sub>CR</sub>, whereas sera 38-7 and 24-1 from patients C.R. and M.J. respectively precipitated >80% and the apparently normal serum 81-5 precipitated >50% of the  $^{125}$ I-labelled p24 at the highest serum concentration tested. Thus, the two highly positive human sera had antibody titres very similar to that of the hyperimmune rabbit serum. The profile of normal serum M.R.G. in Fig. 1 is typical of the results obtained with all the negative sera tested. These results concur with data obtained in an independent study using solid phase radioimmunoassay which showed specific reactivities in these sera towards HTLV<sub>CR</sub> (ref. 14).

reactivities in these sera towards HTLV<sub>CR</sub> (ref. 14).

In view of the past controversy<sup>15</sup> concerning the presence of natural antibodies in human sera reactive with antigens from animal retroviruses, the reactivities shown in Fig. 1 were analysed for their specificity. Various retroviruses and cell

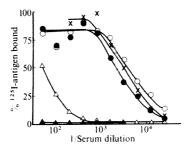

Fig. 1 Immunoprecipitation of <sup>125</sup>I-labelled HTLV<sub>CR</sub> p24 by different human sera. HTLV<sub>CR</sub> p24 was purified and labelled with <sup>125</sup>I as described elsewhere<sup>8</sup>. The labelled p24 (8,000–10,000 c.p.m.) was mixed with two-fold serial dilutions of human sera or a hyperimmune rabbit serum raised against HTLV in a volume of 20 μl of buffer 1 (200 mM Tris-HCl, pH 7.5, 200 mM NaCl, 1 mM EDTA, 0.3% Triton X-100, 0.1 mM phenylmethylsulphonyl fluoride and 2 mg ml<sup>-1</sup> bovine serum albumin). The reaction mixture was incubated for 2 h at 37 °C and overnight at 4 °C. A 20-fold excess of goat anti-human IgG (or goat anti-rabbit IgG when rabbit IgG was the primary antibody) was then added and the volume made up to 500 μl with buffer 1. The samples were incubated for 1 h at 37 °C and an additional 2 h at 4 °C and then centrifuged at 2,500 r.p.m. for 15 min in a Beckman centrifuge. The supernatants were aspirated and the radioactivity in the pellets was counted in an LKB Ultrogamma counter. ♠ Human serum (patient C.R.); ♠, human serum (patient M.J.); △, human serum (wife of patient C.R.); ♠, normal human serum, M.R.G.; ×, rabbit antiserum to HTLV<sub>CR</sub>.

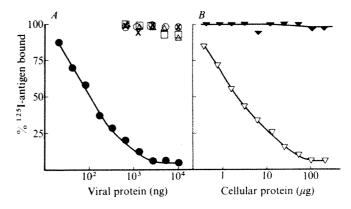

Fig. 2 Specificity of the precipitation of HTLV<sub>CR</sub> p24 by serum of patient M.J. Competition radioimmunoassays were set up using <sup>125</sup>I-labelled HTLV<sub>CR</sub> p24 and a limiting dilution (1:7,500) of the human serum (patient M.J.). Serial dilutions of the unlabelled antigens were preincubated with the serum for 1 h at 37 °C. Labelled p24 (8,000-10,000 c.p.m.) was then added and the reaction mixture incubated and processed as described in Fig. 1 legend. a, Competition by retroviral extracts: ♠, HTLV<sub>CR</sub>; ○, SSV; ×, BaEV; △, SMRV; □—□, BLV. b, Competition by cell extracts: ▽, HUT102 cells producing HTLV<sub>CR</sub>; ▼, HUT78 cells.

extracts were tested for their capacity to compete with the precipitation of <sup>125</sup>I-labelled p24 induced by the positive human sera. Figure 2 shows results obtained with the serum of patient M.J. Simian sarcoma virus, baboon endogenous virus, Mason-Pfizer monkey virus and bovine leukaemia virus failed to neutralize the reactivity of the serum for p24. Only HTLV<sub>CR</sub> effectively competed in the precipitation (Fig. 2a). Similarly, extracts from cells which produce HTLV<sub>CR</sub> totally competed in the precipitation, whereas extracts from a neoplastic human T-cell line (HUT78) which is negative for HTLV<sub>CR</sub> (ref. 8) failed to compete (Fig. 2b). This specificity is very similar to that observed in the precipitation of HTLV<sub>CR</sub> p24 by a hyperimmune serum against disrupted HTLV<sub>CR</sub> (ref. 8). The same strict specificity was observed with all the human sera which showed an immune reactivity with HTLV<sub>CR</sub> p24 (Table 1). Similarly, identical results were obtained whether the immune complex was precipitated with goat anti-human IgG or by the addition of inactivated Staphylococcus aureus cells, indicating that the reactive species in the human sera are intact immunoglobulin molecules.

The extent of immune precipitation of  $^{125}$ I-labelled p24 by the human sera was not affected by the assay conditions used, unlike the situation encountered with human natural antibodies reported to be reactive to envelope glycoproteins of animal retroviruses (refs 12, 13 and data below). The extent and pattern of precipitation of  $HTLV_{CR}$  p24 by human sera were identical, irrespective of whether the immune precipitation medium was supplemented with ovalbumin or bovine serum albumin as a protein carrier (Fig. 3a,b). In contrast, many human sera exhibit strong precipitating activity towards Rauscher murine leu-

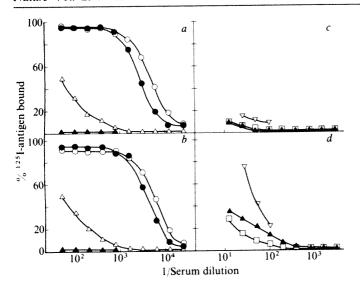

Fig. 3 Effect of buffer composition on the precipitation of <sup>125</sup>I-labelled HTLV<sub>CR</sub> p24 and <sup>125</sup>I-labelled R-MuLV gp70 by human sera. Immuno-precipitation of <sup>125</sup>I-labelled HTLV<sub>CR</sub> p24 and <sup>125</sup>I-labelled R-MuLV gp70 by the human sera subsequence of the first part of the first bovine serum albumin and 0.5% Triton X-100) or in buffer B (buffer A containing 5 mg ml<sup>-1</sup> ovalbumin instead of bovine serum albumin). Labelled antigen (8,000-10,000 c.p.m.) was incubated with twofold serial dilutions of the human sera in 200 µl of the appropriate buffer and the extent of immune precipitation measured as described in Fig. 1 legend. a, b Represent prereplation of HTLV<sub>CR</sub> p24 in buffer A and buffer B respectively. •, Serum of patient C.R.; O, serum of patient M.J.; △, serum of the wife of patient C.R.; A, normal serum. c, d Represent precipitation of R-MuLV gp70 in buffer A and buffer B, respectively.

kaemia virus (R-MuLV) gp70 when the reaction is done in the presence of ovalbumin as the carrier (Fig. 3d). This activity is nearly eliminated if bovine serum albumin is used instead of ovalbumin (Fig. 3c). Such reactivity is also observed with gp70s of other retroviruses and is thought to be directed, not against the polypeptide portions of the gp70 that are virus coded, but against the carbohydrate moieties on the molecule that are introduced by the host cell as a post-transcriptional event, and which are therefore cell-specific and not virus-specific 12,13. This lack of viral specificity is clearly shown by the finding that, unlike the activity towards  $HTLV_{CR}$  p24, all the viruses tested competed totally in the precipitation of R-MuLV gp70 (Table 1).

We have described here a specific immune reactivity in some human sera towards the internal structural antigen p24 of HTLV<sub>CR</sub>, a type C retrovirus, isolated from the T cells of two different patients with T-cell malignancies. Of 84 sera tested, 3 have shown significant reactivity towards this viral antigen. It is possible that other sera contain anti-HTLV<sub>CR</sub> antibodies but were missed because the assay detects only antibodies to the HTLV<sub>CR</sub> core protein, p24. In this regard, use of an envelope antigen of the virus as the probe may show a more representative frequency of natural antibodies in humans towards the virus. These and independent tests using solid phase radioimmunoassay (ref. 14) are the first evidence of a specific immune response to a type C retrovirus in humans. As animal retroviruses can cause T-cell leukaemias and lymphomas, the finding of these antibodies only in sera of people with T-cell neoplasias and in the positive normal case (the wife of the patient from whom HTLV was first isolated), combined with other recent evidence for the presence of this virus in some of these patients, warrants careful consideration of a possible role for HTLV in the origin of these kinds of human leukaemias and lymphomas.

We acknowledge the technical assistance of M. Jarvis and S. Odell and many helpful discussions with M. Robert-Guroff.

# The *v-sis* transforming gene of simian sarcoma virus is a new onc gene of primate origin

Flossie Wong-Staal, Riccardo Dalla Favera, Edward P. Gelmann, Vittorio Manzari\*, Stanislaw Szala, Steven F. Josephs & Robert C. Gallo

Laboratory of Tumor Cell Biology, National Cancer Institute, Bethesda, Maryland 20205, USA

The defective transforming simian sarcoma virus (SSV) and its nondefective helper virus (SSAV) are retroviruses isolated from a fibrosarcoma of a pet woolly monkey. Together with the gibbon ape leukaemia viruses, they are the only group of retroviruses known to cause spontaneous and experimentally induced neoplasia in primates (see refs 1 and 2 for review). Molecular cloning has shown that SSV contains a 1.2-kilobase (kb) transformation-specific viral onc gene (v-sis)3,4 which, like other viral onc genes, is derived from a set of conserved cellular DNA sequences<sup>5</sup>. A human DNA fragment containing sequences homologous to the entire v-sis gene has also been cloned and analysed. We present here experiments carried out on the cloned SSV genome which show that: (1) v-sis is distinct from other viral transforming (onc) genes; and (2) v-sis is derived from a woolly monkey naturally infected once with gibbon ape leukaemia virus (GaLV) and is to date the only onc gene of primate origin.

Different viral onc genes have been known to share a common cellular progenitor. There are many examples of viruses isolated from the same species acquiring the same onc gene, and at least one example of a cellular one gene represented in viruses from two different species (chicken and cat)<sup>7</sup>. To test possible homology between v-sis and other viral onc genes, we digested DNA from a recombinant phage clone (C60) of SSV with the restriction endonucleases BglII or a combination of SalI and PvuII to localize the v-sis sequences on a gel, which we blothybridized8 to 32P-labelled plasmid clones containing onc sequences from different acutely transforming retroviruses. Table 1 summarizes the origin and properties of the probes used. The detailed restriction map of C60 has been published elsewhere<sup>3</sup>. This clone has two copies of the long terminal repeat (LTR) and an inversion involving one LTR and 0.1 kb of adjacent viral sequences. In each case Bg/II or SalI and PvuII generated a 0.65-kb fragment that was highly enriched in v-sis sequences, as demonstrated by the poor detection of this

ND, not determined.

fragment by the SSAV probe compared with the homologous SSV probe (Fig. 1a, b; and see simplified map of C60). None of the other viral onc probes detected the 0.65-kb fragment. Except for Harvey murine sarcoma virus (HaMSV) and Kirsten murine sarcoma virus (KiMSV), the murine or feline probes contained no helper sequences and did not hybridize detectably to any SSV DNA fragment (Fig. 1d). Although the avian viral probes did contain helper sequences, they showed no detectable homology with SSAV-derived sequences (Fig. 1d). The HaMSV and KiMSV plasmids used contained the entire viral genome, and hybridization to the 2.8-kb PvuII fragment or 3.3-kb BgIII fragment of SSV (Fig. 1c) was probably due to cross-reactivity of the LTR sequences of the two viruses.

To ensure that the *onc* genes of HaMSV and KiMSV were indeed unrelated to any portion, especially the 3' region, of *v-sis*, further restriction enzyme analyses were carried out. For these experiments, a clone of SSV (C14) which contained one LTR and no inversion in its genome was used<sup>24</sup>. DNA from C14

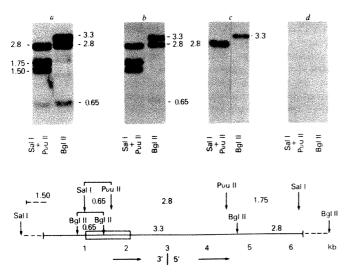

Fig. 1 Lack of homology of v-sis to other viral onc sequences. DNA (40 ng) from a Charon 21A-SSV recombinant phage (C60) was digested with  $Bg\Pi$ I or  $Sa\Pi + Pvu\Pi$  on 1.0% agarose gels and transferred to nitrocellulose filters as described elsewhere  $^6$ . Multiple replicate filters were made and each hybridized to a  $^{32}$ P probe prepared from the cloned DNA after nick translation  $^{23}$ . a, SSV; b, SSAV; c, HaMSV, KiMSV; d, M-MSV $_{onc}$ , FeSV $_{onc}$ : A-MuLV $_{onc}$ : AMV, MC29, ASV(SR). The filters were washed in 1×SSC at 60 °C and autoradiography was carried out for 4–16 h. A simplified map of C60 is shown at the bottom. Sizes are given in kb.

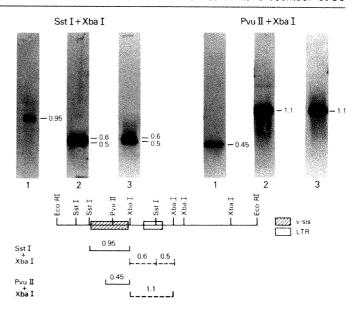

Fig. 2 Assay for homology between a Charon 21A-SSV recombinant phage (C14) and plasmid clones of HaMSV and KiMSV. Triplicate filters containing C14 DNA digested with Sst1 + Xba1 or PvuII + Xba1 were hybridized to <sup>32</sup>P-labelled probes of: (1) p335, a plasmid subclone of the 3' half of a human c-sis gene, (2) HaMSV and (3) KiMSV. A simplified map of C14 indicating the v-sis and LTR sequences is also shown. Sizes are given in kb.

was co-digested with SstI and XbaI or with PvuII and XbaI. These digestions delimited more precisely the boundaries of v-sis and LTR sequences (see map in Fig. 2). To locate more conveniently the 3' region of v-sis, a subclone (p335) derived from a BamHI-BamHI fragment of the human c-sis gene homologous to the 3' two-thirds of v-sis was used as a probe. This clone has no SSAV-related sequences<sup>6</sup>. Replicate filters were hybridized to 32P-labelled pBR322 plasmid clones containing HaMSV and KiMSV genomes. p335 detected a 0.95-kb fragment in the SstI+XbaI digestion and a 0.45-kb fragment in the PvuII+XbaI fragment (Fig. 2), as expected from the map. The HaMSV and KiMSV probes, in contrast, hybridized only to fragments containing LTR sequences (0.6 and 0.5 kb in the SstI+XbaI digest and 1.1 kb in the PvuII+XbaI digest) and not at all to sis-containing fragments. This lack of homology between v-sis and v-Harvey-ras is consistent with our previous demonstration that v-sis and v-Harvey-ras hybridized to distinct sets of sequences in vertebrate DNA<sup>5</sup>. Here we also show that v-sis is distinct from v-Kirsten-ras. Thus, taken together, our results suggested that v-sis was distinct from other viral onc genes. Of particular interest was the lack of homology between v-sis and the M-MSV, HaMSV or KiMSV onc genes. The genetic structure of SSV is most similar to M-MSV in that its gene order is 5'-\(\Delta gag-\Delta env-onc-C-3'\) (ref. 3). Its transformation-specific protein product is a 20,000-molecular weight protein (our unpublished data, and J. Thiel and D. Bolognesi, personal communication), similar in size to the transforming protein (p21) of KiMSV and HaMSV9. Our results suggest that v-sis is distinct from these three rodent-derived onc genes.

All the known viral onc genes are derived from normal host cell sequences that are phylogenetically conserved among vertebrates. Using a non-stringent and sensitive hybridization technique such as Southern hybridization<sup>8</sup>, we have shown that v-sis sequences could detect homologous loci in DNA from chicken to man<sup>5</sup>. Determination of its actual host species of origin, however, would require a more stringent assay of homology. We have subcloned a PstI-PstI fragment of the SSV genome that contains ~250 base pairs (bp) of 5' v-sis sequences and 900 bp of SSAV-derived sequences into the bacteriophage M13. The single-stranded phage DNA was then partially digested with DNase and terminally labelled with <sup>32</sup>P by the kinase

Table 2 Species of origin of p-sis sequences

	S <sub>1</sub> nuclease resistant (c.p.m.)	% v-sis sequences hybridized							
Woolly monkey	11,000	87							
Marmoset	9,200	71							
Gibbon	6,100	54							
Human	5,500	42							
Rat	1,000	8 -							
Cat ,	800	6							

The M13 mp7 recombinant phage was constructed as described previously<sup>22</sup>. The single-stranded phage DNA was purified, 5 µg of the DNA were digested with 0.4 ng DNase I for 15 min at 25 °C, extracted with phenol and dialysed. The partially digested DNA was then treated with bacterial alkaline phosphatase (3 U) at 60 °C for 30 min, extracted with phenol and precipitated in ethanol. The precipitate was collected by centrifugation, and incubated with polynucleotide kinase and 0.2 mCI  $[\gamma^{-32}P]$ ATP (7,000 Ci nmol<sup>-1</sup>) at 37 °C for 30 min. The labelled DNA was purified by three cycles of ethanol precipitation in ammonium acetate buffer. About 400,000 c.p.m. of the labelled probe (~12,000 c.p.m. of v-sis sequences) was hybridized to 500  $\mu$ g of cellular DNA to a  $C_0t$  of >10<sup>4</sup>. Hybridization was monitored by  $S_1$  nuclease resistance as described elsewhere<sup>1</sup>.

reaction<sup>10</sup>. The labelled DNA was hybridized in solution to cellular DNA from tissues of different animals and the resultant hybrids assayed by their resistance to S<sub>1</sub> nuclease<sup>11</sup>. Of all the DNA examined, primate DNA hybridized significantly better than DNA from non-primates (Table 2). Among the primates, the New World monkeys (woolly monkey and marmoset) contained more DNA sequences homologous to v-sis than the Old World apes (gibbon and man) and the highest homology was obtained with woolly monkey DNA. The SSAV genome had no detectable homology to primate DNA either by Southern hybridization<sup>5,6</sup> or liquid hybridization (not shown), and its distant homology to rodent DNA could only be monitored by non-stringent hybridization conditions 12. We conclude that v-sis originated from woolly monkey DNA. The close relatedness of SSAV to different GaLV isolates and the revelation that the woolly monkey that yielded SSV/SSAV co-habited with a gibbon before it developed sarcoma<sup>11</sup> suggest that SSAV was transmitted from the gibbon to the woolly monkey during that period, and that in a single infection event, SSAV had recovered an onc gene from woolly monkey to generate SSV.

Although all viral onc genes thus far identified are conserved among vertebrate species from bird to man, there seems to be some species specificity with respect to the particular onc gene(s) accessible for recombination. For example, the same chicken onc gene (myc) was recovered in four independent recombination events to generate the leukaemia viruses MC29, MH2, CMII and OK10 (ref. 13). The only known example of related cellular onc genes from different species becoming viral onc genes is the relationship between the feline sarcoma virus (Snyder-Theilen and Gardner-Arnstein strains) and avian Fujinami sarcoma virus<sup>7</sup>. Therefore, the genetic arrangement of a particular onc gene may vary between species and may determine its frequency or recombination. As v-sis is the first known one gene derived from a primate, it would be of interest to see whether subsequent primate virus isolates will pick up the same gene.

We thank the following investigators for gifts of cloned DNAs: G. Vande Woude for M-MSV, S. Aaronson for A-MuLV, M. Martin for HaMSV, M. Baluda for AMV, T. Papas for MC29, M. Bishop for SR-ASV and N. Tsuchida for KiMSV.

# Structure of the glycoprotein gene in rabies virus

#### Algis Anilionis, William H. Wunner & Peter J. Curtis

The Wistar Institute of Anatomy and Biology, 36th Street at Spruce, Philadelphia, Pennsylvania 19104, USA

Rables virus; a rhabdovirus, has a single (non-segmented) negative-strand RNA genome which is transcribed on infection to produce five polyadenylated complementary monocistronic mRNA species. Each of the virus-specific mRNAs representing a structural gene of the rables virus genome<sup>1</sup> codes for a virion structural protein which corresponds in size to the apparent coding capacity of its mRNA<sup>2,3</sup>. The glycoprotein gene codes for a membrane-associated molecule which forms spike-like projections on the surface of mature rables virious and is responsible for the induction and binding of virus-neutralizing antibodies to the virus<sup>4-4</sup>. To define the antigenic and immunogenic properties of rables virus glycoprotein, we have cloned a cDNA copy of its mRNA sequence into pBR322 (ref. 7). Here we describe the characterization of the cDNA sequence, which has allowed as to predict several features of the glycoprotein from the deduced amino acid sequence.

The five rabies virus-specific mRNAs for L, G, N, M<sub>1</sub> and M<sub>2</sub> proteins have been characterized by sucrose gradient3 and gel analysis<sup>2</sup>: L mRNA sediments at >28S, glycoprotein (G) mRNA at 18S, nucleocapsid (N) mRNA at 16S and matrix (M1 and M<sub>2</sub>) mRNAs at 12S. For the cloning of the G mRNA, RNA extracted from rabies virus-infected BHK cells was purified by oligo(dT) cellulose chromatography and sucrose density centrifugation. Poly(A) RNA of ~15-20S was used as starting material (thus eliminating the mRNAs for L, M1 and M2 proteins) for the synthesis of double-stranded complementary DNA. Synthesized DNA was inserted into pBR322 at the PstI site by dG-dC tailing (see Fig. 1 legend). Approximately 1% of the tetracycline-resistant colonies screened using 32P-labelled rables virion RNA responded with varying intensities. From 100 colonies that were re-screened, the 20 giving the strongest signals were selected. The size of the plasmids was checked by digestion with BamHI to give linear molecules and with PstI to excise the insert. About half the plasmids contained an additional BamHI site (group A) while the others contained a single BamHI site (group B). This suggested the presence of two different sequences, which we presumed coded for glycoprotein and nucleocapsid protein.

To distinguish between the putative glycoprotein and nucleocapsid protein mRNA-specific plasmids, the insert of a plasmid from each group was isolated by PstI digestion and

Present address: Southern Medical and Pharmacoutical Corporation, 3500 Rant Fletcher Avenne, Sune 321, Temps, Florida 33612, USA

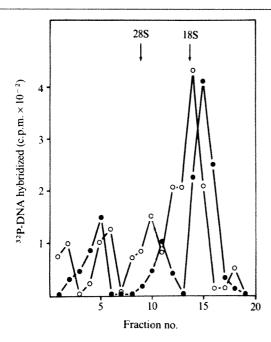

Fig. 1 Hybridization analysis of rabies virus-infected cell poly(A) RNA with rabies recombinant plasmids. Plasmids were constructed as follows: 15-20S poly(A) RNA from rabies virus (ERA strain)-infected cells was transcribed into cDNA using oligo(dT) as primer and AMV reverse transcriptase (supplied by J. Beard), followed by synthesis of double-stranded (ds) cDNA with Escherichia coli DNA polymerase<sup>17</sup>. After S<sub>1</sub> nuclease treatment, ds-cDNA was elongated with dCMP residues by deoxynucleotidyl terminal transferase, and ds-cDNA >1 kbp was selected by sucrose density centrifugation. ds-cDNA tailed with dCMP was hybridized to pBR322 cut with PstI and tailed with dGMP residues, and the recombinant plasmid used to transform E. coli x 1776 (ref. 18). Colonies containing rabies virus-specific sequences were selected by colony hybridization<sup>19</sup> using rabies virion RNA labelled with <sup>32</sup>P by polynucleotide kinase after partial alkali hydrolysis. For hybridization analysis, poly(A) RNA (~130 µg) was heatdenatured at 100 °C for 1 min and centrifuged in a 5-23% sucrose gradient containing 50 mM Tris-HCl pH 7.5, 5 mM EDTA at 25,000 r.p.m. at 10 °C for 16 h in a Beckman SW41 rotor. Each fraction (0.5 ml) from the gradient was diluted 1:60 with water and 1 µl was hybridized with labelled insert (~3,000 c.p.m., specific activity 10<sup>8</sup> c.p.m. µg<sup>-1</sup>) prepared from plasmids A and B. Before hybridization, the probes were heated at 100 °C for 5 min, adjusted to 50% formamide, 0.75 M NaCl, 10 mM HEPES buffer (pH 6.8), 1 mM EDTA, 1 mg ml<sup>-1</sup> yeast RNA, and heated with fractionated poly(A) RNA from rabies virus-infected cells in a total volume of 10 µl at 45 °C for 16 h in paraffin oil. Hybridization was stopped by addition of cold 0.25 M NaCl, 0.03 M sodium acetate (pH 4.5), 1 mM ZnCl<sub>2</sub>. After removal of paraffin oil, S<sub>1</sub> nuclease (100 units) was added and the solution incubated at 37 °C for 45 min. Acid-insoluble counts were determined by trichloroacetic acid precipitation. ○, B; ●, A.

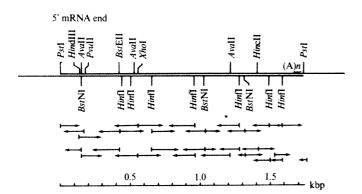

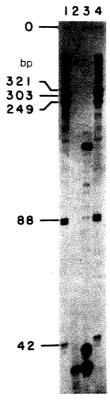

Fig. 2 Restriction map of the insert of pRG. The map was constructed from the size of DNA fragments arising from digestion with combinations of restriction enzymes and estimated by agarose or acrylamide gel electrophoresis 10. The upper set of arrows indicates regions and directions sequenced from the cDNA strand. At the end of the cDNA sequence corresponding to the 5' terminus of the mRNA, there is an oligo(dG-dC) tract of 24 residues with an oligo(dG-dC) tract of 14 residues at the opposite end. Also present at this end is a sequence of poly(dA) which exists in our clone as two lengths of ~50 and 80 bp.

electrophoresis on 1.5% agarose gel<sup>8</sup>. Each insert was labelled by nick-translation<sup>9</sup> and hybridized to individual fractions of poly(A) RNA derived from rabies virus-infected cells and sedimented in a sucrose gradient (Fig. 1). The insert of a group B plasmid hybridized to a mRNA sedimenting at 18S, the location of maximal mRNA activity for the synthesis of glycoprotein, while the insert of group A hybridized to a mRNA sedimenting at 16S, the location of mRNA capable of directing the synthesis in oocytes of nucleocapsid protein (see Fig. 1 in ref. 3). Thus the plasmids of groups A and B were designated pRN and pRG respectively.

Restriction mapping established the size of the inserted DNA of pRG to be ~1.75 kilobase pairs (kbp; Fig. 2). To determine the number of nucleotides which might be missing from the glycoprotein cDNA insert, a small labelled fragment located close to the 5' end of the glycoprotein sequence and bounded by restriction sites for *PvuII* and *HindIII* was hybridized to 18S poly(A) RNA from rabies virus-infected cells. Incubation of the hybrid formed between glycoprotein mRNA and labelled DNA

Comparison of lengths of the glycoprotein cDNA clone and its mRNA. The glycoprotein gene sequence was restricted with PvuII, labelled by  $[\gamma^{-32}P]ATP$  with polynucleotide kinase, and subsequently digested with HindIII. The 5'-labelled 36-bp fragment located close to the 5' terminus of the glycoprotein sequence was isolated on a 5% polyacrylamide (0.1% bisacrylamide) gel in 50 mM Tris-borate pH~8.3,~1 mM EDTA, eluted and dried. The  $^{32}$ P-labelled fragment was then denatured in 20  $\mu$ l of 80% (v/v) formamide by heating at 100 °C for 3 min. A sample of 18S poly(A) RNA (10 µg) from rabies virus-infected cells was dried down with 20 µl of solution containing 0.4 M NaCl, 20 mM HEPES buffer pH 6.8, and 1 mM EDTA pH The solution of denatured 32P-labelled DNA was added to the dried RNA and incubated at 60, 58, 56 and 54 °C for 1 h at each temperature. After annealing, the mixture was transferred to 100 µl cold 0.3 M sodium acetate pH 5.5 and precipitated by 2.5 vol ethanol at -20 °C. The precipitated nucleic acids were dissolved in 40  $\mu$ l of 50 mM Tris-HCl pH 8.3, 10 mM MgCl<sub>2</sub>, 35 mM KCl, 30 mM  $\beta$ -mercaptoethanol, 0.5 mM each of the four deoxynucleoside triphosphates, 200 µg ml<sup>-1</sup> bovine serum albumin, 12.5 µg ml<sup>-1</sup> actinomycin D and AMV reverse transcriptase (12 U), and incubated at 37 °C for 90 min. After precipitation from the reaction mixture with ethanol, the nucleic acids were dissolved in 4  $\mu$ l 80% formamide, 50 mM Tris-borate pH 8.3, 1 mM EDTA, 0.1% xylene cyanol FF and 0.1% Bromophenol blue and heated at 90 °C for 1 min before loading on to a 8% polyacrylamide (0.4% bisacrylamide) gel containing 50% (w/v) urea, 100 mM Tris-borate pH 8.3, 2 mM EDTA. Labelled nucleic acids were detected by autoradiography using an intensifying screen at -70 °C. Lanes 1 and 4, labelled size markers; lane 2, labelled 36-bp fragment bounded by Pvull and HindIII; lane 3, labelled 36-bp fragment elongated by AMV reverse transcriptase. O, origin.

Fig. 4 DNA sequence of the mRNA sense strand and the deduced amino acid sequence for rabies virus glycoprotein (ERA Numbers strain). parentheses refer to the amino acids counted from N-terminal lysine the residue of the mature glycoprotein located 20 amino acids from the presumed initiation codon. A shaded hydrophobic domain close to the C-terminal end is presumed to be the transmembrane segment. Asterisks mark three possible carbohydrate attachment sites based on the presence of Asn-X-Ser and Asn-X-Thr as described in the text. Boxes show the initiation codon (ATG) and termination codon (TGA).

fragment with avian myeloblastosis virus (AMV) reverse transcriptase extended the primer to the 5' terminus of the glycoprotein mRNA. Products of the reaction were resolved on a denaturing gel and identified by autoradiography (Fig. 3). Apart from the labelled primer fragment (actual length 36 nucleotides), the major products were ~40 and 165 nucleotides long. The 40-nucleotide band presumably arose by filling in the HindIII site recreated by the annealing of PvuII-HindIII DNA strands, while the 165-nucleotide band resulted from the extension of the primer which was hybridized to glycoprotein mRNA. As the PvuII site is located 129 bp from the 5' terminus of the cloned glycoprotein sequence (excluding the dG-dC tail of 24 bp), our results indicate that the cloned glycoprotein sequence is missing only ~35 nucleotides from the 5' terminus of the glycoprotein mRNA.

The complete nucleotide sequence of the glycoprotein cDNA (see Fig. 4) was determined by the Maxam and Gilbert technique<sup>10</sup> using both 5'- and 3'-labelled restriction fragments derived from both strands defined by the sites indicated in Fig. 2. From the nucleotide sequence, a polypeptide 524 amino acids long was deduced, beginning with an initiation codon—ATGlocated 8-10 nucleotides from the 5' end of the clone. The other two reading frames contained numerous stop codons, such that the longest polypeptide which can be derived from them is <50 amino acids long.

The first six amino acid residues of the mature glycoprotein, NH<sub>2</sub>-Lys-Phe-Pro-Ile-Tyr-Thr-, have been identified by direct amino acid sequence analysis of purified rabies virus (ERA strain) glycoprotein, as well as the C-terminal sequence Thr-Arg-Leu (C.-Y. Lai and B. Dietzschold, unpublished results). These sequences are located in the deduced sequence 20-25 and 522-524 residues from the putative initiating methionine. The initial 19 amino acids that precede the N-terminal lysine of the glycoprotein presumably represent a signal peptide as they are predominantly hydrophobic. An uninterrupted hydrophobic domain of 22 amino acids, bounded by lysine 439 (numbered from the N-terminal lysine) and two arginines at positions 462 and 463 near the carboxy-terminal region of the predicted polypeptide, is similar to the proposed transmembrane segment of Semliki Forest virus (SFV) glycoprotein<sup>11</sup>. A relatively long sequence of 44 charged and uncharged residues extends from the presumptive transmembrane domain to the C-terminal Leu 505 (compare with the viral glycoproteins of  $SFV^{11}$  and influenza virus<sup>12</sup>). This apparent hydrophilic cytoplasmic domain of the rabies glycoprotein may provide a site for strong interaction with the viral matrix  $(M_2)$  and nucleocapsid proteins.

The deduced amino acid sequence contains four carbohydrate acceptor sites as defined by the sequence Asn-X-Ser and Asn-X-Thr; three of these are located on the N-terminal side of the proposed transmembrane segment. Three carbohydrate chains have been found on the rabies virus glycoprotein of the ERA strain<sup>13</sup>, which agrees with the predicted number of carbohydrate attachment sites excluding Asp 465 within the putative cytoplasmic domain.

The absence of the sequence AAUAAA, present in eukaryotic polyadenylated mRNA14, in the 3'-noncoding region of rabies G mRNA and vesicular stomatitis virus mRNAs15 presumably reflects the role of virus-associated proteins in polyadenylation of these mRNAs<sup>16</sup> in place of host enzymes.

The cloned cDNA of rabies glycoprotein mRNA was readily identified and distinguished from nucleocapsid protein cDNA clones by (1) size selection of the poly(A) RNA identified by its ability to direct synthesis of glycoprotein in microinjected oocytes<sup>3</sup>; (2) hybridization with labelled purified rabies virion RNA; and (3) hybridization with glycoprotein mRNA as indicated by the correspondence of the profiles of hybridized RNA and RNA with translational capacity for glycoprotein. The accuracy of the cloned glycoprotein cDNA sequence was confirmed by the agreement between the predicted amino acid sequence and that determined by direct N-terminal and Cterminal amino acid analysis.

We thank Dr G. Threlfall for preliminary restriction data and Erik Whitehorn and Chris Brewer for technical assistance. Although interferons (IFNs) were originally described as proteins conferring antiviral resistance to eukaryotic cells<sup>1</sup>, various additional biological effects have since been attributed to them, including inhibition of cell proliferation and modulation of the immune response2. More recently it was recognized that interferons from different sources have similar amino acid sequences, suggesting their evolutionary relationship. When the sequences of human interferons of the  $\alpha$  and  $\beta$  type were aligned to give maximum homology, a largely conserved region was found near the carboxyl terminus of the molecules<sup>3,4</sup>. The homology of human leukocyte IFN-\alpha\_1 and human fibroblast interferon between positions 111 and 166, for instance, was 40%. As conservation of segments of polypeptide chains during evolution may indicate their functional importance<sup>5</sup>, we synthesized three carboxyl-terminal fragments of human IFN- $\alpha_1$  (ref. 6) ranging in size from 33 to 96 amino acid residues. If the folding of these fragments was similar to that of the corresponding segments in the intact protein, it was conceivable that they had biological activity and that antibodies raised against the synthetic fragments cross-reacted with natural interferon. Such antibodies could be used for the affinity purification of human interferon produced in bacteria and for radioimmunoassays. As we show here, none of the fragments had antiviral activity. A mouse monoclonal antibody prepared against a 56-residue fragment also bound intact IFN- $\alpha_1$  and IFN- $\alpha_2$  without neutralizing their antiviral effect. Thus, this antibody, directed against a largely conserved region, may show substantial cross-reactivity within the interferon protein family.

Three carboxyl-terminal fragments of human IFN- $\alpha_1$  (ref. 6), comprising residues 134-166, 111-166 and 71-166, were synthesized by the solid-phase method<sup>7-9</sup>. Experimental details are given for the 56-residue fragment because antibodies have previously been raised only against an extensively purified sample of this polypeptide. The sequence of the 56-residue fragment is shown in Fig. 1.

After deprotection and cleavage of the synthetic product from the solid support, the sulphydryl group of Cys 139 was blocked

§ Present address: Laboratory of Molecular Genetics, National Institute of Neurological and Communicative Disorders and Stroke, National Institutes of Health, Bethesda, Maryland 20205, USA.

by reaction with iodoacetamide. In natural IFN- $\alpha_1$  this cysteine residue may form a disulphide bond with Cys 29, analogous to IFN- $\alpha A^{10}$ . The carboxamidomethylated fragment was purified on Sephadex G-50 (Fig. 2) and silica gel 60 and had the following amino acid composition (values expected are in parentheses): CM-Cys 1.0 (1), Asp 3.0 (3), Thr 2.9 (3), Ser 4.5 (5), Glu 5.7 (6), Pro 1.0 (1), Ala 4.1 (4), Val 2.7 (3), Met 2.0 (2), Ile 3.0 (3), Leu 8.0 (8), Tyr 2.8 (3), Phe 1.0 (1), Lys 5.0 (5), Trp 0.9 (1), Arg 6.7 (7). The synthetic 56-residue fragment of IFN- $\alpha_1$  was homogeneous on TLC in n-butanol/acetic acid/pyridine/water ( $R_F = 0.74$ ) and on thin-layer electrophoresis in 2 M HCOOH, 2 M urea at pH 2.0. Its aromatic region circular dichroism (CD) spectrum and fluorescence emission spectrum were typical of tryptophan-containing polypeptides.

The most striking physicochemical property of the 56-residue interferon fragment was its low solubility above pH7. Interferon 111-166 has a net charge of +6 whereas the entire IFN- $\alpha_1$ molecule has a net charge of -3. The natural protein contains 17 aromatic amino acid residues whereas the synthetic fragment contains 5, including 3 of the 4 tyrosines and 1 of the 2 tryptophans. Twenty-six of the 56 residues of the synthetic fragment are hydrophobic, with a calculated hydrophobicity index<sup>11</sup> of 31.9, lower than that of insulin (35.7), a protein of similar size. This suggests that the solubility properties of the interferon fragment cannot be explained by its amino acid composition.

The structure of synthetic interferon 111–166 in solution was investigated using CD. Analysis of the far-UV spectrum of a 0.1% solution of the synthetic fragment in 0.01 M phosphate, 0.09 M NaCl, pH 5.0, yielded values of 24 and 36% for  $\alpha$ -helix and  $\beta$ -sheet content respectively, using the method of Provencher and Glöckner<sup>12</sup>, in contrast to the secondary structure predicted for the corresponding region of IFN- $\alpha_1$  (65%  $\alpha$ -helix and 20%  $\beta$ -sheet)<sup>13</sup>. Interferon 111-166 was stable to urea denaturation up to a denaturant concentration of ~4 M but was unfolded by 8 M urea. The CD spectrum indicated that in the latter condition the molecule approximates a random coil. This process was almost fully reversible (>90%), the native CD spectrum being restored by diluting out the denaturant. This suggests that the fragment is capable of considerable selforganization, producing a structure that, in the light of the immunological results, is probably close to that in the intact interferon molecules.

Polyclonal antisera raised in rabbits or mice against the synthetic 56-residue fragment did not neutralize the antiviral activity of human leukocyte interferon. However, they seemed to bind to interferon, as binding to the fragment (assayed in a solid-phase radioimmunoassay as described in Table 1 legend) was competitively inhibited by Escherichia coli-derived leukocyte IFN- $\alpha_1$  or  $-\alpha_2$ , interferon from human buffy coat lymphocytes and virus-induced mouse interferon, but not by unrelated proteins (data not shown). This suggested that monoclonal

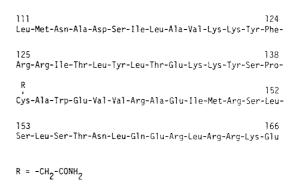

Fig. 1 Amino acid sequence of the synthetic carboxyl terminal 56-residue fragment of IFN-α<sub>1</sub> based on the nucleotide sequence of cloned cDNA<sup>6</sup>

The synthetic human IFN- $\alpha_1$  111-166 was intraperitoneally injected into three BALB/c mice as 50  $\mu$ g of protein mixed with complete Freund's adjuvant. A first booster injection with the same dose of antigen in incomplete Freund's adjuvant was given after 3 weeks. A second booster, after another interval of 4 weeks, consisted of 50  $\mu$ g of protein per animal injected intraperitoneally with incomplete adjuvant and 50  $\mu$ g of protein per animal dissolved in phosphate-buffered saline (PBS) and given intravenously. After 3 days, the spleen cells of the three animals were pooled and  $1.5 \times 10^8$  cells were fused to  $0.75 \times 10^8$  cells of the mouse myeloma cell line Fo using polyethylene glycol of molecular weight 4,000 as the fusing agent. Hybrid cells were selected for growth in hypoxanthine/aminopterin/thymidine medium. Supernatant fluids of cell cultures were screened for the presence of specifically binding antibodies in a solid phase radioimmunoassay. The 56-residue interferon fragment was dissolved in PBS at a concentration of 5  $\mu$ g ml<sup>-1</sup> and was adsorbed to polyvinylchloride microtitre plates. Additional protein binding sites were blocked by a 5-h exposure to 3% solution of ovalbumin. The supernatant fluids were exposed to the wells of microtitre plates for 4 h at room temperature. The presence of fragment-binding immunoglobulins was detected by assaying the radioactivity bound to the wells exposed to a rabbit anti-mouse immunoglobulin serum together with radiolabelled *S. aureus* protein. Cells of initially positive cultures were cloned twice by a limiting dilution technique and injected into female BALB/c mice. Ascitic fluids, diluted 1:1,000, were tested as described above. The 33- and 96-residue fragments of interferon were adsorbed to plates as described for the 56-residue peptide. *E. coli-derived* human leukocyte IFN- $\alpha_1$  and - $\alpha_2$ , each at a concentration of 10  $\mu$ g ml<sup>-1</sup> in PBS and of 10% purity, were similarly adsorbed to the plates. Each value shown represents the mean counts per min from th

antibodies<sup>14</sup> prepared against the 56-residue fragment recognize antigenic sites on the corresponding segments of intact interferon molecules.

Three BALB/c mice were immunized against the 56-residue fragment, their spleen cells pooled and fused to cells of the mouse myeloma line Fo (ref. 15), and hybrid cells selected for production of fragment-binding antibodies as described in Table 1 legend. Twenty-eight hybrid cell cultures obtained from the fusion of  $1.5 \times 10^8$  spleen cells with  $0.75 \times 10^8$  myeloma cells were found to produce proteins that bound to the fragment. Sixteen of the originally positive cultures were cloned twice; of these clones, five produced proteins that cross-reacted with the unrelated antigen ovalbumin, the remaining 11 synthesizing specific antibodies of subclasses IgG1, IgG2a and IgG3, all containing  $\kappa$  light chains.

Further analysis of the binding properties of these specific antibodies in a radioimmunoassay using the synthetic carboxylterminal 96- and 33-residue fragment and bacterially produced IFN- $\alpha_1$  and - $\alpha_2$  (Table 1) suggested that the hybridoma antibodies fell into three classes: antibodies of clone III/21 bound to all fragments and both interferons; antibodies of clones I/7, II/3, II/11, II/14, VII/8, XXI/5 and XXIV/11 bound to various degrees to all fragments but not to the interferons; the products of clones I/5, II/20 and III/17 bound exclusively to the 56-residue fragment. Thus, at least three different epitopes are recognized on the 56-residue fragment, one of which is accessible to a distinct monoclonal antibody also on natural interferon.

Ascitic fluid from mice bearing tumours of clone III/21 was tested for neutralization of the antiviral effect of IFN- $\alpha_1$  and  $-\alpha_2$  on three different target cells (human larynx carcinoma line CCL 23, bovine kidney cells and mouse L-cells) on which both interferons show cross-reactivity<sup>16</sup>, using Mengo virus, vesicular stomatitis virus or encephalomyocarditis virus as challenge. No reduction of the interferon titres was found after preincubation with ascitic fluid from clone III/21 diluted 1:20, whereas at a dilution of 1:10 the ascitic fluid neutralized a maximum of 3 IFN units and at 1:5 it neutralized a maximum of 9 IFN units. This minor reduction of the interferon titres, however, may have been partly caused by ascitic fluid components other than the monoclonal antibody. The fact that the antibodies raised against the synthetic 56-residue fragment essentially did not neutralize the interferon activity was compatible with the observation that

none of the synthetic fragments inhibited viral growth in the cell lines mentioned above.

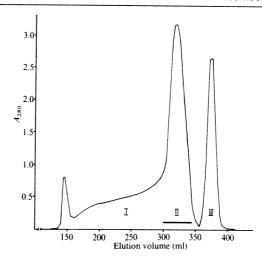

Human leukocyte interferon extracted from bacteria is largely contaminated by prokaryotic proteins. As mouse hybridomas secreting monoclonal antibodies to interferon represent a rich source of material for the preparation of affinity columns, we investigated the efficacy of affinity chromatography for the purification of human interferon produced in bacteria.

Mice were injected with cells of clone III/21 and their ascitic fluids, binding to IFN- $\alpha_2$ -coated plates with a titre of  $10^{-5}$ pooled. The IgG fraction was isolated and coupled to CNBractivated Sepharose 4B. A column with a capacity of  $2 \times 10^7$ reference units of IFN- $\alpha$  per ml of gel was loaded with partially purified IFN-α<sub>2</sub> (E. coli) (Fig. 3, slot 2) which had a specific activity of  $3 \times 10^6$  units per mg of protein. The column was eluted with phosphate-buffered saline (PBS, pH 7.2), followed by McIlvaine's buffer (pH 2.6). At neutral pH most of the interferon was retained. The material eluting at pH 2.6 was enriched in interferon (4.8 × 10<sup>7</sup> units per mg of protein) and low molecular weight (M<sub>r</sub>) proteins and was almost free of high molecular weight proteins as shown by SDS-polyacrylamide gel electrophoresis (Fig. 3, slot 3). Re-chromatography of this material in identical conditions gave purified interferon with a specific activity of 8.8×10<sup>7</sup> units per mg of protein. Gel electrophoresis of the fraction eluting at pH 2.6 showed a very strong interferon band corresponding to a M, of 19,400, a minor band at  $M_r$  17,800, and a very weak band at  $M_r$  13,000 (Fig. 3, slot 4).

The synthetic carboxyl-terminal 56-residue fragment of human IFN- $\alpha_1$  was not homogeneous: although its amino acid composition as well as chromatographic and electrophoretic purity were satisfactory (the good recovery of tryptophan is particularly noticeable), minor deviations from the target sequence caused mainly by deletions at various stages of the synthesis could not be excluded. Further purification of the 56-residue fragment will involve affinity chromatography on an antibody column and HPLC. However, the CD measurements indicated that the synthetic IFN 111-166 had a considerable amount of stable structure.

Synthetic fragments of natural proteins may be suitable for raising antisera that cross-react with the parent molecules 17,18. The present study describes the first production of a monoclonal antibody against a synthetic polypeptide, the linear carboxyl-

Fig. 2 Fractionation of the carboxamidomethylated carboxyl-terminal 56residue fragment of human IFN-α<sub>1</sub> (105 mg) on a Sephadex G-50 column (97.5 × 2.4 cm) in 0.05 M CH<sub>3</sub>COOH. I, disulphide dimer and aggregates; II, monomeric carboxamidomethylated 56-residue fragment (the bar indicates the elution range of the fraction that was re-chromatographed); III, excess iodoacetamide. The carboxamidomethylated 56-residue fragment was obtained as follows<sup>7-9</sup>. Tertiary butyloxycarbonyl (Boc) amino acids were coupled in a threefold molar excess based on the amount of carboxyl terminal glutamic acid esterified to the resin. Each coupling reaction was repeated with a twofold molar excess of the Boc amino acid. The side chains of methionine and tryptophan were unprotected. To prevent their alkylation or oxidative cleavage during the acid deprotection step, 10% anisole and 2%  $\beta$ -mercaptoethanol were present in the deblocking mixture (40% trifluoroacetic acid in CH<sub>2</sub>Cl<sub>2</sub>) after addition to the peptide resin of Boc-Met and Boc-Trp, respectively. At the end of the synthesis the yield of protected 56-residue peptide resin was 85.8%. The synthetic polypeptide was deprotected and cleaved from the resin by anhydrous HF in the presence of anisole (sixfold molar excess per protecting group) and free tryptophan (twofold molar excess per tryptophan residue) at 0 °C for 30 min and then extracted by 1 M CH<sub>3</sub>COOH. After lyophilization it was dissolved in 0.05 M NH4HCO3, 8 M urea and dialysed against 0.05 M NH4HCO3. Decreasing urea concentration caused the synthetic 56-residue polypeptide to pre-

cipitate, and hyphilization gave the crude interferon fragment. The yield of the cleavage step was 82.9%. The synthetic fragment was treated with a 100-fold molar excess of  $\beta$ -mercaptoethanol in 5 M urea at pH 4 overnight and the reduced protein was isolated by gel filtration on Bio-Gel P-2 in 0.1 M CH<sub>3</sub>COOH. To the pooled protein fractions 0.05 M NH<sub>4</sub>HCO<sub>3</sub> was added to give a final protein concentration of 1mg mi<sup>-1</sup>. The sulphydryl group of Cys 139 was blocked by reaction with a 10-fold molar excess of iodoacetamide at pH 7 and the product was fractionated on Sephadex G-50 as shown above. After re-chromatography the carboxamidomethylated 56-residue fragment was obtained in 52.5% yield based on the amount applied to the first column. It was purified further by adsorption chromatography on silica gel 60 using n-butanol, acetic acid, pyridine and water (15:3:10:12) as eluant

terminal 56-residue fragment of human IFN- $\alpha_1$ . The crossreactivity of antibodies of clone III/21 with the synthetic interferon fragments 134-166 and 71-166 and with complete human IFN- $\alpha_1$  and  $-\alpha_2$  (derived from E. coli) suggested that there was a common antigenic site of very similar fold that was (largely) located between residues 134 and 166 of the interferon sequence, and accessible on the natural interferon molecules. Monoclonal antibodies that bound the synthetic fragments only, probably recognized structures that were either absent or not accessible on natural interferons.

A small library of monoclonal antibodies against leukocyte interferons already exists. A monoclonal antibody described by Secher and Burke<sup>19</sup> was raised against human leukocyte interferon and selected for its capacity to neutralize the antiviral effect of this protein. It did not cross-react with human fibroblast or mouse interferon<sup>20</sup>. As the antibodies prepared to the synthetic carboxyl terminal 56-residue fragment of IFN- $\alpha_1$  were essentially non-neutralizing, the binding site of the monoclonal antibody of Secher and Burke was either located between residues 1 and 110 or was constituted by amino acid residues scattered over a large part of the interferon sequence including

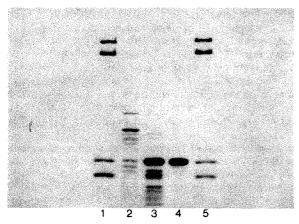

Fig. 3 Gel electrophoretic analysis of E. coli-derived human IFN- $\alpha_2$  before and after affinity chromatography on a column containing a monoclonal antibody prepared against the carboxyl terminal 56-residue fragment of human IFN-α<sub>1</sub>. Gel, 0.1% SDS-17% polyacrylamide; 25 μg of protein were applied per slot. Staining was with Coomassie brilliant blue. 1, 5, Protein markers (from top to bottom: bovine serum albumin, catalase,  $\beta$ -lactoglobulin, cytochrome c). 2, Partially purified interferon applied to the antibody column. 3, Material eluted with McIlvaine's buffer, pH 2.6; after neutralization it was re-chromatographed on the antibody column. 4, Rechromatographed material eluting at pH 2.6; the strong band at molecular weight 19.400 is interferon.

the region from 111 to 166. It was also possible that a neutralizing site at the carboxyl terminus of human leukocyte interferon was not present on the synthetic fragment because of conformational differences. Another monoclonal IgG specific for human leukocyte interferon was obtained by Montagnier et al.21, while Staehelin and co-workers22 prepared 13 monoclonal antibodies to human leukocyte interferon which gave distinct binding patterns with purified interferon species and of which were non-neutralizing. The monoclonal antibody described here bound (at least) human IFN- $\alpha_1$  and - $\alpha_2$  derived from E. coli and was used to prepare an affinity column from which purified human IFN- $\alpha_2$  (E. coli) with a specific activity of ~10<sup>8</sup> units per mg of protein was isolated. Ultimately, a whole library of monoclonal antibodies may be available to map the antibody and receptor binding sites of the various interferons.

We thank Professor J. Lindenmann for stimulating discussions and Professor C. Weissmann for his continued interest and supply of cloned species of IFNs. We acknowledge the helpful advice of Drs H. Binz, O. Haller and H. Hengartner from whom we also received the myeloma cell line, and thank Dr S. Provencher for providing a copy of the CONTIN program for analysis of the CD results, M. Welti, C. Wanner-Kaufmann and M. Gröbke-Wittmer for technical assistance, A. Honegger for help with computing and B. Straub for assistance with the CD measurements. The work at the Biochemisches Institut was supported in part by a grant to B.G. from the Schweizerische Nationalfonds.

# Carrier-dependent and carrierindependent transport of anti-cancer alkylating agents

John E. Byfield & Paula M. Calabro-Jones

Division of Radiation Oncology, University of California Medical Center, San Diego, California 92103, USA

While it is understandable that proliferating cells should be more sensitive than resting cells to antimetabolites—drugs that derange DNA synthesis—It is not so obvious that other anticancer drugs, in particular the alkylating agents, should act in the same way. The greater sensitivity of proliferating cells to such agents is not confined to malignant tissues: normal haematopoletic cells show increased susceptibility after recruitment into cell division4. Moreover, the various alkylating agents have different effects on proliferating nonmalignant cells; in normal bone marrow, recovery is more rapid and greater after treatment with some drugs (for example, cyclophosphamide and nitrogen mustard) than others (such as nitrosourens and mitomycin C). We now provide evidence in support of the hypothesis that there are two distinct groups of alkylating agent: those whose uptake into the cell depends on a membrane transport mechanism (that is, carrier-dependent) and those whose uptake is not so dependent (carrier-independent).

An assay which uses the mitogen phytohaemagglutinin (PHA) to induce proliferation in tissue culture of human peripheral T lymphocytes<sup>7-9</sup> was developed for these experiments<sup>10</sup>. It can be seen (Fig. 1) that <sup>3</sup>H-thymidine uptake was very low before PHA stimulation but increased steadily (as measured by continuous label incorporation) in the 18 h after its addition. Therefore, in this assay, unstimulated human peripheral T lymphocytes are considered a 'resting' cell population and after 18 h of exposure to PHA they are considered to be actively proliferating. To test the effects of alkylating agents on these two populations of cells, various drug concentrations were added either 60 min before or 18 h after PHA stimulation. An initial experiment used melphalan (L-phenylalanine mustard), which has recently been shown to be actively taken up by an amino acid transport system in both rodent cells and human lymphocytes 11-13. Figure 1 shows the effect of a 60-min exposure to melphalan at various periods (between 0 and 26 h) after PHA stimulation. Initially, melphalan caused only ~30% death of resting human peripheral Tlymphocytes, but its toxicity steadily increased as PHA-induced proliferation increased, resulting in a maximum of ~90% death 8 h after addition of PHA.

We then determined quantitatively the cytotoxicity of various alkylating agents and X rays, using a series of increasing drug concentrations to obtain reasonably complete (2-3 log death) survival curves. In each case the cells were exposed to the agent for 60 min (an arbitrary exposure time) either at time 0 (resting cells just before PHA exposure, solid circles in Figs 2 and 3) or 18 h after PHA-induced proliferation (cycling cells, open circles in Figs 2 and 3). We obtained two clearly distinguished survival patterns. The first of these we term carrier-dependent (see Fig. 2). Carrier-dependent toxicity is characterized by dose-dependent cell death but with a substantially greater shoulder on the survival curve of resting cells. The shoulder is reduced or eliminated when the cells are exposed to the carrier-dependent agent after induction of cell cycling. Melphalan, nitrogen mustard and cis-dichlorodiammineplatinum (CDDP) all gave this pattern. These three agents are highly water-soluble and two are known to be transported into cells by membrane carriers (melphalan by amino acid carriers 11-13 and nitrogen mustard by a choline carrier<sup>14,15</sup>). We have also found that amino acids can protect cells against CDDP, suggesting that the latter is probably also taken up by an amino acid transport mechanism<sup>16</sup>, which may explain its nephrotoxicity<sup>17</sup>. A fourth water-soluble alkylating agent, phosphoramide mustard (the active form of cyclophosphamide), proved almost inert (at concentrations up to 100 µg ml<sup>-1</sup>) against both resting and cycling human T cells, a feature which may explain its well-documented differential sparing of T cells in vivo<sup>18</sup>.

The second survival pattern, which we term carrier-independent toxicity, is shown in Fig. 3. All the carrier-independent

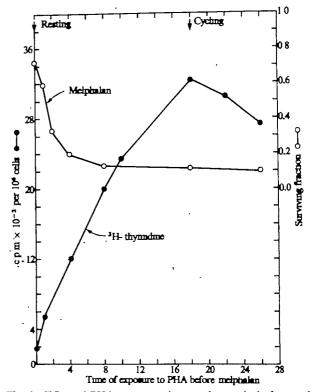

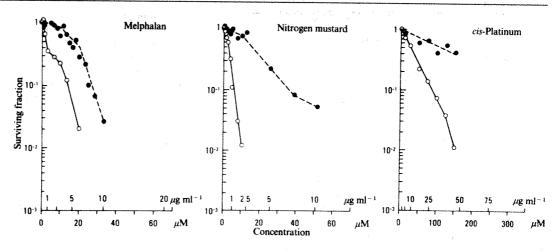

Fig. 1 Effect of PHA exposure time on the survival of normal peripheral T lymphocytes exposed to melphalan -1) for 1 h (O) and on the incorporation of <sup>3</sup>H-thymidine human (4 µg ml" continuous label (.). The assay procedure for determining drug cytotoxicity of normal human T lymphocytes was as follows. Peripheral blood from a healthy adult was collected with 50 U ml heparin and the mononuclear cells were isolated by Ficoll-Paque (Pharmacia) gradient centrifugation. Cells from the interphase containing >95% lymphocytes were washed three times in Hank's balanced salt solution (HBSS; Gibco) and resuspended at 106 cells ml<sup>-1</sup> in McCoy's 5a medium containing 15% heat-inactivated fetal bovine serum (FBS; Gibco). Aliquots (1 ml) of the cell suspension were seeded into 16 × 125 mm tubes (Falcon 3033); replicate tubes were used for determining cell survival or DNA synthesis. PHA (HA15 Wellcome) was freshly prepared at 2% in complete medium and 1 ml added to each tube at time 0; one set of tubes (♠) contained [Me-³H]thymidine (43 Ci mmol⁻¹, 10 μCi ml⁻¹; Amersham). At the times indicated, one tube from each set was removed and DNA synthesis determined (1). The other tube (0) was exposed to melphalan (NSC 8806, freshly prepared at 4 µg final concentration in complete medium) for 1 h, followed by washes and re-exposure to PHA for the remaining time necessary to complete an 18-h PHA exposure for colony formation. The cells were then washed in HBSS and syringe-resuspended in 2 ml complete medium to disaggregate the cells. To each tube were added 1 ml of 1% PHA in complete medium and 2 ml 2.6% methylcellulose in complete medium. Cells were plated in 35-mm dishes (Falcon) to give a final concentration per plate of  $5\times10^5$ cells in 0.2% PHA, 1.0% methylcellulose. PHA-induced colonics containing >50 cells were counted with an inverted microscope at day 7 Plating efficiencies for non-treated controls in both the resting and cycling sets were consistently ~0.1%. Surviving fractions were determined by assigning a value of 1.0 to the untreated controls. DNA synthesis was determined by the method of Evans and Norman  $^{52}$ . Briefly, the labelled cells were washed three times in cold PBS containing  $100~\mu \mathrm{g}~\mathrm{m}\mathrm{l}^{-1}$  thymidine (Sigma) and resuspended in 10 ml cold PBS. Cell number was determined and cells placed on Millipore GS 0.22-µm filters. Filters were washed with 5% trichloroacetic acid, then 95% ethanol, and air-dried overnight and placed in viels with 10 ml scintillation fluid.

Fig. 2 Effect of carrierdependent agents on the survival of normal human lymphocytes before (
) and after PHA stimulation for 18 h (O). The overall assay procedure is outlined in Fig. 1 legend. The two different time points for the 60-min exposure are indicated by arrows in Fig. 1. All drugs were freshly prepared before use. Melphalan (NSC 8806) was dissolved 10 mg ml (9:1). ethanol/HCl Nitrogen mustard (Mustargen) was obtained as a 1 mg ml<sup>-1</sup> solution in solution in

PBS; cis-platinum (Platinol; Bristol) was obtained as 10 mg lyophilized sample and reconstituted with sterile double distilled water. All dilutions were made in complete media.

drugs gave identical survival curves for resting and cycling cells and all are highly lipid-soluble. Those drugs which showed this pattern (Fig. 3) include the nitrosureas 1,3-bis(2-chloroethyl)-1-nitrosourea (BCNU) and methyl-CCNU [1-(2-chloroethyl)-3-trans-(4-methyl-cyclohexyl)-1-nitrosourea] (plus CCNU, data not shown), procarbazine, busulfan (data not shown), mitomycin C, an amphipathic agent freely soluble in both water and lipids<sup>19</sup>, and ACNU [1-(4-amino-2-methyl-pyrimidin-5-yl)-methyl-3-(2-chloroethyl)-3-(nitrosourea)], an amphipathic nitrosourea with delayed marrow toxicity<sup>20</sup>. These results

suggest that the extent of lipid solubility (which would override a carrier mechanism) may dictate the type of cell survival pattern. X rays (whose entry into cells is independent of any 'carrier') also showed a carrier-independent pattern. As these nitrosoureas<sup>21,22</sup> and mitomycin C<sup>23</sup> are bifunctional alkylating agents and cross-link DNA in a manner similar to that of the classical mustards, it seems unlikely that it is the nature of the molecular damage which results in the different survival patterns. Repair of DNA damage in resting cells (that is, before cycling) also cannot explain the relative resistance of resting cells

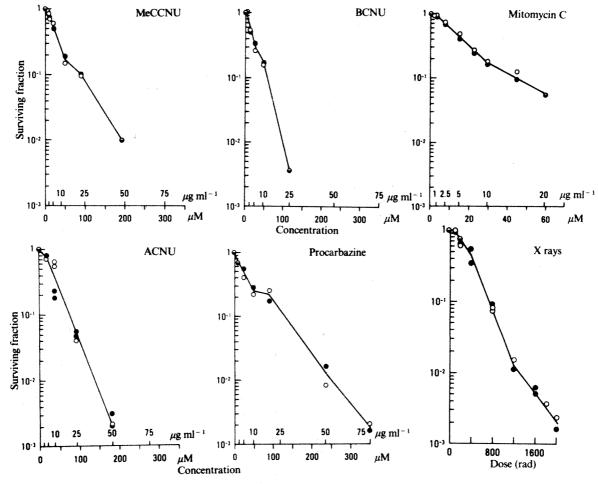

Fig. 3 Effect of carrier-independent agents on the survival of normal human lymphocytes before (●) and after PHA stimulation for 18 h (○). The assay procedure is outlined in Fig. 1 legend. All drugs were freshly prepared before use. Methyl-CCNU (MeCCNU; NSC 95441), BCNU (NSC 409962), ACNU (NSC D245382) and procarbazine (NSC 77213) were dissolved at 1 mg ml<sup>-1</sup> in absolute ethanol. Mitomycin C (Mutamycin; Bristol) was obtained as 5 mg in sterile distilled water. All dilutions were made in complete media. X-ray exposure was at room temperature in air on a Picker orthovoltage 280 keV machine, using an HVL 1.0 mm copper filter with an output of 150 rad min<sup>-1</sup>.

to carrier-dependent drugs, as the carrier-independent alkylating agents would be expected to show the same evidence of cellular repair. The feature which dictates the shape of the survival curve and governs the (relative) independence/dependence of toxicity on the cell's proliferative state seems to be the drug's ability to penetrate the cell by simple diffusion into cellular lipids and lipoproteins<sup>24,25</sup>.

We believe these two patterns are reflected in the two recovery patterns shown by bone marrow after exposure to alkylating agents. When delivered as a bolus, the recovery of marrow from carrier-dependent agents is usually fairly rapid such that cyclical therapy, can be repeated about every 21 days 5.26-28. The equivalent administration of a lipid-soluble nitrosourea<sup>20,29</sup>, mitomycin C<sup>30,31</sup>, or X rays<sup>28</sup> is followed by a considerably prolonged marrow recovery period of 4-6 weeks. In the rat this delayed recovery pattern has recently been shown (for CCNU) to relate to marrow stem-cell killing independent of the proliferative state of the pluripotential marrow stem cells<sup>32</sup>. Clinically, all the carrier-independent agents (those cited in Fig. 3 legend, plus CCNU and busulfan) are associated with delayed marrow recovery and also with cumulative marrow damage, that is, a steady irreversible depletion of marrow reserve with progressive dosage<sup>5,20,33-35</sup>. On the other hand, the carrier-dependent agents produce relatively less marrow damage and show much more rapid marrow recovery<sup>6,28</sup>. The only apparent exception to this rule is melphalan<sup>31,36</sup>; we believe this discrepancy is due to the prolonged administration schedule that has been used for melphalan in man.

This binary model may also be relevant to the means by which tumour cells develop resistance. It predicts that a significant source of resistance to carrier-dependent alkylating agents could stem from somatic mutations that yield cells whose membrane carriers are either fewer in number or have reduced drug affinity. A contribution to resistance by reduced transmembrane transport has recently been shown for melphalan<sup>13</sup>. As CDDP seems to be transported by a similar pathway<sup>16</sup>, its partial cross-resistance with melphalan<sup>37,38</sup> is perhaps expected.

For carrier-independent agents, cell uptake seems to be independent of membrane events and the existence of somatic mutants conferring significant resistance at the membrane level is unlikely. This suggests that 'resistance' to carrier-independent alkylating agents can stem only from intracellular sources, for example, by reduced intracellular activation of the agent (if such is needed), selection of cells with greater DNA repair mechanisms<sup>38–42</sup> or by nonspecific protective effects such as the selection of mutants with elevated thiol levels<sup>43</sup>.. The reduced tendency of carrier-independent drugs to induce resistance<sup>44</sup>, and their high activity in some rodent models 45, make carrierindependent agents superficially attractive. However, the data in Fig. 3 indicate that such drugs do not have any true differential cytotoxicity between resting and cycling normal stem cells. These properties reduce their overall clinical potential considerably as regimens exploiting the considerable recruitment potential of resting normal tissues are precluded.

These data suggest that the proliferation dependency of alkylating agent cytotoxicity stems from two unequal and disparate sources: (1) a major dependence, limited to carrierdependent drugs, on enhanced transport of the drug into the cell because it is, in part, a stereochemical analogue of a normal compound (for example, amino acid, choline) used in cell biosynthesis; (2) a minor dependence (shared by both carrierdependent and carrier-independent drugs) attributable to inherent sensitivity of replicating DNA to alkylating agents. We recently showed that the cytotoxicity exerted by alkylating agents seems to be a function of the number of DNA replicons that encounter unrepaired alkylated sites on the DNA. These data, together with recent studies 47 on the mechanism of recovery from CDDP damage of resting tissue culture cells suggest this to be the molecular basis for the enhanced sensitivity of cycling cells to both carrier-dependent and carrier-independent alkylating agents.

There are several implications of this model: (1) carrierdependent agents are likely to be more useful clinically than those that are carrier-independent, and new, useful carrierdependent alkylating agents can probably be synthesized that will exploit membrane carriers not available to present agents (for example, bases, sugars, other amino acids, polyamines); (2) the minimal dose of each carrier-dependent agent used in each treatment cycle should probably be at or just beyond the point where the differential effect of the agent against resting versus cycling cells is first maximized; (3) treatment schedules which include and serially alternate several carrier-dependent agents known to be lacking in cross-resistance are predicted to be most useful, as this would minimize the outgrowth of drug-resistant (membrane) mutants<sup>48,49</sup>; (4) the inclusion of carrier-independent agents in these schedules is likely to be harmful, except in the rare event where a specific advantage such as central nervous system penetration or hypoxic activation<sup>50</sup> exists, or where the net tumour volume is minimal and ('adjuvant') non-selective chemotherapy might be effective; (5) therapies designed to enhance proliferation-dependent carrier-dependent drug killing (for example, combinations of carrier-dependent alkylating agents and clinically tolerable methylated xanthines, for example see ref. 51) might also usefully be examined.

We thank the Irvin Stern Foundation for financial support.

Streptozotocin, which produces diabetes mellitus in experimental animals <sup>1-3</sup>, has been reported to reduce the level of NAD in pancreatic islets <sup>4,5</sup> and to inhibit islet synthesis of proinsulin <sup>6</sup>. The decrease in NAD is due to increased NAD degradation mediated by islet nuclear poly(ADP-ribose) synthetase <sup>7,8</sup>. Evidence suggests that poly(ADP-ribose) synthetase is activated when DNA is fragmented <sup>9-17</sup>. Here we describe that both streptozotocin and alloxan, which also produces experimental diabetes mellitus <sup>1,2</sup>, cause DNA strand breaks which stimulate nuclear poly(ADP-ribose) synthetase, thereby depleting intracellular NAD and inhibiting proinsulin synthesis in isolated pancreatic islets of rats.

Islets isolated from rat pancreas were incubated with streptozotocin or alloxan for 5-20 min in Krebs-Ringer's bicarbonate medium and velocity sedimentation of DNA from the islet cells was carried out in an alkaline sucrose gradient. DNA from islets incubated for 10 min without the diabetogenic agents was recovered as a single peak near the bottom of the gradient, the position at which undamaged DNA sediments (Fig. 1a, e). However, after only 5 min incubation with 2 mM streptozotocin or 1 mM alloxan, a considerable amount of DNA sedimented as a broad peak in the middle of the gradient with a concomitant decrease in undamaged DNA (Fig. 1b, f); after 10-20 min incubation, the DNA was almost completely fragmented (Fig. 1c, d, g, h). The effect of the two agents on islet DNA fragmentation was dose dependent. These results clearly indicate that streptozotocin and alloxan produce strand breaks in islet DNA.

DNA fragmentation in mammalian cells has been reported to activate nuclear poly(ADP-ribose) synthetase<sup>9-15</sup>, and there is direct evidence 16,17 that poly(ADP-ribose) synthetase purified from bovine thymus is activated only when the enzyme is bound to fragmented or nicked DNA. Therefore, we prepared a nuclear fraction from islets incubated in conditions causing breaks in islet DNA, and assayed poly(ADP-ribose) synthetase activity. As shown in Fig. 2a, b, both streptozotocin (2 mM) and alloxan (1 mM) induced a two- to threefold increase in islet poly(ADP-ribose) synthetase activity, with a peak at 10 min. Streptozotocin has also been shown to cause an approximately 1.2-3-fold increase in nuclear enzyme activity of Physarum polycephalum<sup>18</sup> and HeLa cells<sup>19</sup>; and as much as a 10-fold increase in enzyme activity has been observed in y-irradiated permeable cells<sup>20</sup>. The procedure used to isolate the nuclei is reported<sup>10,20</sup> to cause DNA strand breaks and to activate poly(ADP-ribose) synthetase. We therefore examined a DNA sedimentation profile of the islet nuclear fraction. We found that the isolation procedure per se caused some DNA breaks, but that nuclear DNA from islets incubated with alloxan or streptozotocin was fragmented to a greater degree than that induced by the nuclear isolation procedure alone (data not shown). This indicates that the low, two- to threefold increase in islet nuclear poly(ADP-ribose) synthetase activity was probably due to the high background of DNA breaks resulting from the isolation procedure.

\* To whom correspondence should be addressed.

Cellular NAD content was reduced by either 2 mM streptozotocin or 1 mM alloxan within 20 min of incubation (Fig. 2c, d), and remained almost unaltered for 60 min. There was striking temporal correlation between the decrease in level of islet NAD and the increase in islet poly(ADP-ribose) synthetase activity. These results indicate that both alloxan and streptozotocin cause DNA strand breaks which result in an increase in poly(ADP-ribose) synthetase activity, thereby depleting islet NAD level. However, it has been suggested that alloxan may not be toxic to islets because it decreases the NAD level<sup>2.3</sup>.

Next, we examined the effect of inhibitors of poly(ADP-ribose) synthetase on streptozotocin- or alloxan-reduced islet NAD content. The inhibitors used were nicotinamide and picolinamide, which are potent inhibitors of islet nuclear poly(ADP-ribose) synthetase<sup>7</sup>. The results are shown in Table 1. Alloxan (1 mM) decreased islet NAD level to 18% of the control level (without alloxan). Nicotinamide (2 mM) or picolinamide (2 mM) completely abolished the alloxan-induced decrease in islet NAD level. As previously described<sup>5,7</sup>, the same was true for the decrease in islet NAD level induced by streptozotocin. Addition of nicotinamide or picolinamide alone produced only a slight increase in islet NAD level.

The ability of islets to synthesize proinsulin is considered a crucial marker for evaluation of diabetogenicity of alloxan and streptozotocin<sup>21,22</sup>. As shown in Table 2, 1 mM alloxan reduced proinsulin synthesis to 9% of the control level; nicotinamide (2 mM) or picolinamide (2 mM) reversed this decrease to 35% or 27% of the control value. The decrease in proinsulin synthesis induced by 0.5 mM alloxan (30% of the control) was almost completely abolished by nicotinamide or picolinamide. The decrease in proinsulin synthesis induced by streptozotocin (1 or 2 mM) was also significantly reversed by the addition of either nicotinamide or picolinamide, as described elsewhere<sup>7</sup>. In addition to these *in vitro* experiments with isolated rat islets, *in vivo* experiments on rats confirmed that nicotinamide and picolinamide prevent development of alloxan- as well as streptozotocin-induced diabetes (unpublished data).

This study demonstrates that streptozotocin and alloxan cause DNA strand breaks to stimulate nuclear poly(ADP-ribose) synthetase, thereby depleting intracellular NAD and inhibiting proinsulin synthesis. Inhibitors of islet nuclear poly(ADPribose) synthetase such as nicotinamide and picolinamide were found to reverse the reduction in NAD level and also the inhibition of proinsulin synthesis. These inhibitors may prevent the diabetogenic action of alloxan and streptozotocin by inhibiting NAD degradation through poly(ADP-ribose). Other species of poly(ADP-ribose) synthetase inhibitors, such as 3aminobenzamide, 3-nitrobenzamide and 3-methoxybenzamide, were found to protect against the depression of proinsulin synthesis induced by streptozotocin or alloxan (H.Y., A. Kawamura and H.O., in preparation). Methylxanthines may protect against the action of alloxan on islets23 in a similar way, because they also have been reported to inhibit poly(ADPribose) synthetase<sup>24,25</sup>

Thiols<sup>26</sup> and radical scavengers<sup>27</sup> can also protect against the diabetogenic action of alloxan. It has been suggested that hydroxyl radicals generated from alloxan mediate its diabetogenic action<sup>27-29</sup>. More recently, we observed that strand breaks in islet DNA by alloxan were abolished in the presence of superoxide dismutase (Y.U., H.Y. and H.O., in preparation). Thus it is likely that the free radicals generated from alloxan damage islet cell DNA, resulting in activation of poly(ADP-ribose) synthetase.

The increase in islet poly(ADP-ribose) synthetase activity induced by streptozotocin or alloxan resulted in a significant depletion of islet NAD content. This reduction in intracellular NAD to such a non-physiological level may severely affect islet cell functions, including proinsulin synthesis. In addition, certain viruses or physical factors such as  $\gamma$  rays, which are known to cause DNA strand breaks and to stimulate poly(ADP-ribose) synthetase<sup>11-15,30,31</sup>, may be expected to be aetiological agents of insulin-dependent diabetes<sup>8</sup>.

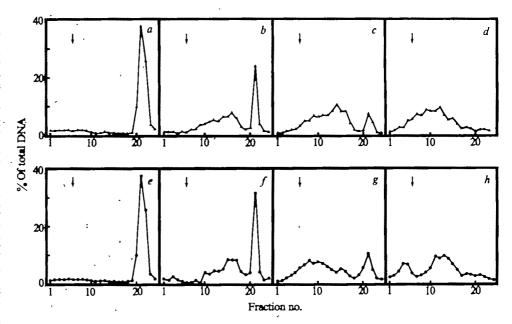

Table 1 NAD content of islets incubated in the presence of alloxan or streptozotocin with or without the addition of nicotinamide or picolinamide

Addition	Total NAD in PCA extract (pmol)	<sup>14</sup> C-NAD in PCA extract (c.p.m.×10 <sup>4</sup> )	% Recovery	Islet NAD content (pmol per islet)
None	351	4.16	93.2	2.84 (100)
Alloxan (1 mM)	141	4.37	97.9	0.52 (18)
Alloxan (1 mM) and nicotinamide (2 mM)	369	4.26	95.5	2.94 (104)
Alloxan (1 mM) and picolinamide (2 mM)	364	· 4.35	97.6	2.81 (99)
Streptozotocin (2 mM)	116	4.10	92.0	0.34 (12)
Streptozotocin (2 mM) and nicotinamide (2 mM)	365	4.25	95.4	2.91 (102)
Streptozotocin (2 mM) and picolinamide (2 mM)	380	4.40	98.6	2.93 (103)
Nicotinamide (2 mM)	395	4.29	96.1	3.19 (112)
Picolinamide (2 mM)	377	4.19	94.0	3.09 (109)

Batches of 100 islets were incubated at 37 °C for 20 mm and NAD content of the islets determined as described in Fig. 2 legend.  $^{14}$ C-NAD  $(4.46 \times 10^4 \text{ c.p.m.}, 92.1 \text{ pmol})$  was added to each sample before disruption of the islets, and the recovery of  $^{14}$ C-radioactivity in the final preparation used to correct the NAD value for overall recovery. Numbers in parentheses are islet NAD content as a percentage of NAD content in cells without any additions.

Fig. 1 Sedimentation profiles in an alkaline sucrose gradient of DNA from salets incubated with streptozotochi or alloxan. Pancreatic salets of Langerhans were iso-lated by the method of Okamoto et al. 22 from male Wistar rats weighing 200-250 g, which were fed ad libition. Batches of 100 islets were incubated for 5-20 min at 37 °C m 100 µl Krebs-Ringer's bicarbonate medium, pH 7.4, supplemented with 5 mM sodium pyruvate, 5 mM sodium fumarate, 5 mM sodium gluta-mate, 2 mg ml<sup>-1</sup> bovine serum albumin (BSA) and 2.8 mM glucose in an atmosphere of 95% O<sub>2</sub>/5% CO<sub>2</sub> (refs 21, 32) Streptozotocin (Upjohn) and allowen monohydrate (Wako Pure Chemical Industries) were dissolved in distilled water just before addition because of their relatively short half lives 1.2. After incubation, islets were suspended in  $50 \, \mu l$  of cold 0.9% saline and immediately layered over 0.5 ml lysis solution (1 M NaOH, 0.01 M EDTA, 1% (v/v) Triton X-100) that had just been layered over 14.8 ml of a 5-20% (w/v) linear sucrose gradient containing 0.3 M NaOH, 0.7 M NaCl and 0.01 M EDTA. On the bottom of each gradient was a 1 ml 80% (w/v) sucrose shelf. The

. . .

loaded gradients were placed in the dark at room temperature for 30 min, then centrifuged at 26,000 r.p.m. at 20 °C for 200 min in a Beckman SW27.1 rotor. After centrifugation, fractions of 33 drops were collected from the gradient. DNA in each fraction was precipitated by adding 2 ml of 20% cold trichloroacetic acid (TCA) with 200 µg BSA as carrier. The precipitate was washed 3 times with cold TCA, once with cold 0.1 M potassium acetate m ethanol, there with ethanol, then assayed for DNA content by a finorimetric method<sup>33</sup>. Each point represents the percentage of total DNA recovered; recovery was between 85 and 100%. A, DNA from silets incubated without streptoxotoch for 100 min (a) and with streptoxotocm (2 mM) for 5 min (b), 10 min (c) and 20 min (d).  $\blacksquare$ , DNA from silets incubated without alloxan for 10 min (a) and with alloxan (1 mM) for 5 min (f), 10 min (g) and 20 min (h). Sedimentation was from left to right. Arrow indicates the position of a bacteriophage  $\lambda$  DNA (3.2×10<sup>7</sup> molecular weight, New England BioLabs).

Fig. 2 Effect of streptozotocin or alloxan on poly(ADP-nbose) synthetise activity and NAD content of pancreatic islet cells. Batches of 300 islets were incubated for 0-60 mm at 37 °C in conditions described in Fig. 1 legend. After incubation, nuclear fractions were prepared from islets and assayed for poly(ADP-ribose) synthetise activity as described previously? The DNA content of each islet nuclear fraction was determined by a fluorimetric method. The properties activity as described previously? The DNA content of each islet nuclear fraction was determined by a fluorimetric method. The properties activity at 0 mm (10.9 pmol poly(ADP-ribose) synthesized per 10 mm per μg islet nuclear DNA). a, Poly(ADP-ribose) synthetises activity in islets incubated with 2 mM streptozotocin (Δ); b, poly(ADP-ribose) synthetises activity in islets incubated with 1 mM alloxan (O). For determination of silet NAD content, batches of 100 islets were incubated for 0-60 min after which they were disrupted by sonication in 1 ml of cold 0.5 M perchloric acid (PCA). The scad-soluble extract of islets was brought to pH 5 0 with KOH, and NAD content in the extract, determined as described elsewhere. The values were corrected for overall recovery by the addition of 14C-NAD (see Table 1 legend), and related to NAD content at 0 min (2.62 pmol NAD per sitel). c, NAD content in islets incubated with 1 mM alloxan (②).

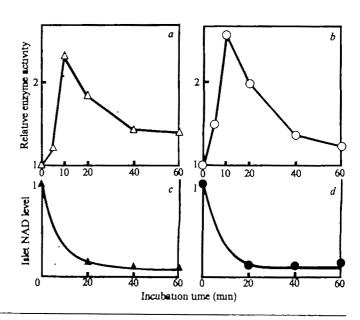

Table 2 Effect of nicotinamide or picolinamide on depression of proinsulin synthesis induced by alloxan or streptozotocin

Addition	<sup>3</sup> H-proinsulin synthesized (c.p.m. per h per islet)
None	3,410 (100)
Alloxan (1 mM)	307 (9)
Alloxan (1 mM) and nicotinamide (2 mM)	1,194 (35)
Alloxan (1 mM) and picolinamide (2 mM)	921 (27)
Alloxan (0.5 mM)	1,009 (30)
Alloxan (0.5 mM) and nicotinamide (2 mM)	3,372 (99)
Alloxan (0.5 mM) and picolinamide (2 mM)	2,496 (73)
Streptozotocin (2 mM)	1,187 (35)
Streptozotocin (2 mM) and nicotinamide (2 mM)	2,868 (84)
Streptozotocin (2 mM) and picolinamide (2 mM)	2,568 (75)
Streptozotocin (1 mM)	2,114 (62)
Streptozotocin (1 mM) and nicotinamide (2 mM)	3,096 (91)
Streptozotocin (1 mM) and picolinamide (2 mM)	3,045 (89)
Nicotinamide (2 mM)	3,584 (105)
Picolinamide (2 mM)	3,342 (98)

Batches of 30 islets were preincubated at 37 °C for 5 min in 100 µl of Krebs-Ringer's bicarbonate medium containing 2.8 mM glucose in the presence or absence of the chemicals as indicated, then incubated for 60 min with the addition 100 μl of medium containing 10 μCi <sup>3</sup>H-leucine (specific activity 122 Ci mmol<sup>-1</sup>; NEN) and 37.2 mM glucose. The final concentration of glucose was 20 mM, at which proinsulin comprises more than one-half the total proteins synthesized de novo in islets and gives a major peak on SDS-polyacrylamide gel electrophoresis<sup>22</sup>. Incubated islets were washed three times with cold Hank's solution, sonicated in 200 µl of 60 mM Tris-phosphoric acid buffer, pH 6.8, containing 1% SDS, 5% 2-mercaptoethanol and 10% glycerol, and heated at 100°C for 2 min. An 80-µl aliquot of the heated sample was submitted to SDS-polyacrylamide gel electrophoresis. The amount of proinsulin synthesized was calculated by summing the <sup>3</sup>H radioactivity incorporated in the proinsulin fractions<sup>22</sup>. Numbers in parentheses are values for proinsulin synthesis as a percentage of that in islets incubated without any additions.

# Intramolecular flexibility in phenylalanine transfer RNA

#### Stephen C. Harvey\* & J. Andrew McCammon†

\* Biophysics Section, Department of Biomathematics, University of Alabama in Birmingham, Birmingham, Alabama 35294, USA † Department of Chemistry, University of Houston, Houston, Texas 77004, USA

Yeast tRNAPhe is an L-shaped molecule, where each arm is a short segment of double-helical RNA. Examination of the crystal structure has suggested that the molecule may be hinged, perhaps in the region where the anticodon stem meets the D stem1, or where the two arms of the molecule meet2. Because tRNA interacts with a variety of macromolecules during protein synthesis, and because it performs various functions in addition to its role in protein synthesis<sup>3</sup>, the idea of a hinge is attractive: such conformational flexibility would facilitate functional flexibility. Here we present the results of a theoretical study of the bending of  $tRNA^{Phe}$  about the proposed hinge at the junction of the two arms2, applying the conformational energy calculation method used previously to examine flexibility in lysozyme4 and in DNA5. The model is surprisingly flexible, swivelling with two degrees of freedom through angles as large as 30° at an energetic cost of only a few kcal per mol. These energies are comparable with that of a few hydrogen bonds, suggesting that solvent conditions and interactions with other molecules are important in modulating structure and flexibility.

The molecule is modelled on a computer by specifying the coordinates of all the atoms as determined crystallographically, the molecular topology (which atoms are bonded to each other) and a set of empirical energy functions<sup>6,7</sup> for all the bond lengths, bond angles, dihedral angles, nonbonded contacts (both van der Waals and electrostatic) and hydrogen bonds. Then, treating the two arms as essentially rigid and specifying the location of the hinge or swivel between them, one arm is rotated about that point in increments of 3°; partial structural relaxation is allowed by energy refinement after each bending increment. The resulting sets of coordinates are subjected to several hundred cycles of steepest-descent energy refinement, and the difference between

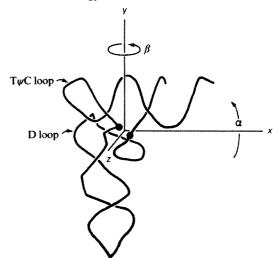

Fig. 1 Backbone of tRNA<sup>Phe</sup>, showing D and TψC loops, coordinate system centred between phosphates P8 and P49 ( ) and the two degrees of freedom. The coordinate system is not that of the crystal structure but has been chosen so that the xy plane is the least-squares best fit plane in the sense that the sum of the squares of the atomic distances from the plane is a minimum. True bending is represented by  $\alpha$ , measuring rotations about the z axis, while  $\beta$ designates swinging, with rotations about the y axis. Positive values of  $\alpha$  swing the arms apart and push the D and T $\psi$ C loops together; positive values of  $\beta$  keep the arms at right angles and pull the D and  $T\psi C$  loops apart.

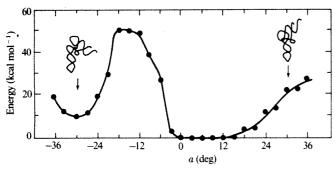

Fig. 2 Dependence of energy on bend angle  $\alpha$ . The crystallographic structure defines  $\alpha=0^\circ$  and the backbone conformations are indicated for  $\alpha = \pm 30^{\circ}$ . The swing angle is unchanged  $(\beta = 0^{\circ})$ during the bending. In Figs 2 and 3, for clarity, negative energies are shown as E = 0; no values below -2 kcal mol<sup>-1</sup> were observed. and because this is about the limit of resolution and the scatter was random (no clear minima were observed), we do not consider the negative values to be significant.

the energies of the bent and unbent models is assumed to be the energy cost of bending.

For this study, we used the 2.5 Å crystallographic structure of Jack et al. 7,8 obtained from the Brookhaven Protein Data Bank9. The empirical energy parameters are essentially those of Levitt<sup>5,16</sup>, as subsequently modified for tRNA<sup>7</sup>, but partial electrostatic charges<sup>11</sup> and approximate corrections for solvent dielectric effects<sup>12</sup> have been included. Neither Mg<sup>2+</sup> nor any other cation has been included, as the study was intended to assess the intrinsic molecular flexibility; we hope to examine the effects of polyvalent cations in future work. There are 79 hydrogen bonds in the model, including the 56 interbase bonds of the cloverleaf secondary structure, 12 bonds between O2' of one ribose and an oxygen atom (O4' or O5') of the successive ribose, and 11 tertiary bonds. This represents all the commonly accepted hydrogen bonds<sup>13</sup> except for 10: 7 bonds between the D and T $\psi$ C loops (2 between G18 and  $\psi$ 55; 3 between G19 and C56; 1 between G57 and R18; 1 between G57 and R19) and 3 within the T $\psi$ C loop (2 between T54 and A58; 1 between G57 and R55). The interloop bonds are proposed to serve as a catch mechanism which opposes bending, while the bonds within the  $T\psi C$  loop were found to become highly distorted as the loop folds to accommodate the bending motions. As these 10 tertiary hydrogen bonds are believed to be among the most sensitive to changes in temperature, pH, ionic strength and concentration of polyvalent cations<sup>14</sup>, they are likely candidates for modulating flexibility. Breaking these bonds requires 22 kcal mol<sup>-1</sup>

After a preliminary examination of various bending motions about several prospective points, we concentrated on the softest bending modes (Fig. 1). The molecule swivels about the region near P8 and P49, with bases 1-7 and 49-76 comprising the upper arm and bases 8-48 comprising the lower. As movement arises from the distortion of several bond angles and dihedrals and the energy minimization algorithm relaxes those distortions by moving several neighbouring atoms, the swivel is not truly a discrete point. Two macroscopic degrees of freedom have been examined, corresponding to the angles  $\alpha$  (true bending, with the upper arm rotating about the z axis relative to the fixed lower

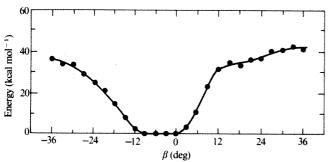

Fig. 3 Dependence of energy on swing angle  $\beta$ , with  $\alpha = 0^{\circ}$ .

arm) and  $\beta$  (swinging, with the upper arm rotating about the y axis while keeping at a right angle to the lower arm). In this study, these two degrees of freedom have been examined separately; a detailed analysis of motions which combine bending and swinging will be reported elsewhere.

Figures 2 and 3 show the results, giving the calculated potential energies for bending and swinging respectively. The most surprising result is that the molecule swivels over an appreciable range of angles using relatively little energy: for <3 kcal mol<sup>-1</sup> it covers a range of about 15° in each direction, while over 30° is covered for <20 kcal mol<sup>-1</sup>.

Because these energies represent less than that contained in 10 hydrogen bonds, a number which could easily be made or broken in interactions either with the solvent or with other macromolecules, such interactions clearly could modulate both the overall shape and flexibility of the molecule. While these results do not prove that tRNA Phe is flexible (especially as the solvent is not explicitly treated in the model), they do suggest that there are no large steric or electrostatic forces within the molecule which oppose swivelling. Consequently, we consider it quite likely that tRNAs sometimes have conformations quite different from the familiar L shape and that flexibility can be induced by moderate changes in solvent conditions.

Also interesting is the anisotropy of the forces which oppose the swivelling. The strongest forces (the steepest slopes in Figs 2, 3) are those resisting closing ( $\alpha < 0$ ) and swinging in one direction  $(\beta > 0)$ ; they arise from the fact that these two motions pull apart the stack of bases G19-G57-G18-m<sup>1</sup>A58 that stabilizes the interaction between the D and T $\psi$ C loops, whereas motions in the other directions ( $\alpha > 0$  and  $\beta < 0$ ) maintain that stacking. The 35-55 kcal mol<sup>-1</sup> required to break the stack of bases is an upper limit, as our steepest-descent minimization algorithm probably does not fold the loops into their lowest-energy conformations as they are separated, but it is approximately what would be expected for a stack of four purines, with base stacking interactions of 5-15 kcal per mol per stacked pair 15.1

During the closing motion, the energy drops below  $\alpha < -18^{\circ}$ , as the stacks G19-G18 and G57-m1A58 are formed and as favourable nonbonded interactions are obtained in the inside of the elbow, where many atoms are brought together by the motion. As a more careful folding of the molecule during bending might substantially reduce the height of the energy barrier in Fig. 2, our results give a conservative estimate of the intrinsic flexibility of tRNA<sup>Phe</sup>, and the molecule may bend even more easily than indicated here.

The flexibility revealed by this study is consistent with the thermal motion observed by crystallographers 7,17 , who reported that atoms near the ends of the arms move more than those near the elbow. The specific biological functions of this flexibility remain to be established, but these motions may facilitate interactions between tRNA and other macromolecules, and tRNA may assume different conformations at different steps in protein synthesis.

# MATTERS ARISINO

#### Importance of cardiac cell membranes in vanadateinduced NADH oxidation

WE have reported previously that purified cardiac cell membranes with high (Na++K+)ATPase activity have significant NADH-vanadate reductase activity. In our experiments, we used calf cardiac cell membranes prepared as described elsewhere<sup>2</sup>, but similar results were obtained with cell membranes from cat and human ventricles and from human erythrocytes. Increasing concentrations of Na<sub>3</sub>VO<sub>4</sub> (0.01-1 mM) in the presence of 10 mM imidazole/HCl buffer pH 7.25, 1.25 mM NADH and 0.1-0.2 mg cell membrane protein caused a concentration-dependent oxidation of NADH (followed photometrically by continuous recording at  $A_{366}$ ), which was virtually absent when heat-denatured cell membranes were used. A more detailed analysis of these experiments has been published elsewhere3

Recently, Vyskočil and co-workers<sup>4</sup> reported that vanadate-induced oxidation of NADH does not require a specific enzyme. Moreover, they did not observe a vanadate-dependent oxidation of NADH in the presence of membrane fractions from rat heart and other tissues (skeletal muscle, brain and liver). They found that NADH oxidation in the presence of vanadate proceeded without cardiac cell membranes in the presence of several buffers, except imidazole/HCl, in which the reaction was completely inhibited. Although so far we agree with these results of Vyskočil et al.4, we tested the vanadate-NADH reaction using rat heart membranes and again found vanadate-dependent oxidation of NADH in the presence of membrane fractions. Thus we maintain that cardiac cell membranes (also from rat) contain a heatsensitive NADH-oxidoreductase that is stimulated by vanadate in the presence 10 mM imidazole/HCl. Several authors<sup>5-7</sup> have found a NADH-oxidizing enzyme in plasma membranes of rat liver, rat skeletal muscle and other organs of various species.

A possible reason for the failure of Vyskočil et al. to detect the vanadatedependent oxidation of NADH in the presence of membrane fractions from rat heart might be the procedure used to isolate the membranes or the preparation of the vanadate solution. We used a solution of Na<sub>3</sub>VO<sub>4</sub> that was freshly prepared on each day of the experiment in twice distilled water and adjusted to pH 7.25 with HCl.

VYSKOČIL ET AL. REPLY—The following remarks are pertinent to the discrepancies between our experimental data<sup>1</sup> and those of Erdmann et al.<sup>2</sup>.

First, the preparation of the vanadate solutions may well have caused some of the differences. In previous papers<sup>2</sup>, Erdmann et al. did not describe the preparation of the vanadate stock solutions; other papers3-6 have shown that the degree of polymerization of vanadate species depends on the pH and concentration of vanadate in the solution, and on temperature and ionic strength. Particularly at vanadate concentrations of 0.1-10 mM) and within the pH range 7.0-8.0, it is uncertain which species predominates, as dimeric, trimeric and decameric clusters may be formed. The possibility cannot be excluded that Erdmann et al. worked with vanadate solutions in which decameric anions prevailed, even when freshly prepared. However, we observed no effect in imidazole solution when a stock solution of vanadate (V) was made with NaOH7. On the other hand, in the decavanadate solution prepared according to Choate and Mansour4, we also observed vanadate-dependent oxidation of NADH in the presence of rat skeletal muscle membrane fractions in an imidazole buffer. It is possible (see ref. 6) that membrane fractions promote the NADH-vanadate (V) reactions by preferential binding of reduced vanadyl (IV), which is consistent with Rubinson's statement<sup>6</sup> that if free ligand(s)—probably some thermolabile components of membranes—are present in a pHbuffered solution, then vanadate (V) ions will tend to be reduced to vanadyl (IV) forms (which bind to the ligand more strongly than the V form) provided there is some electron-donating reagent such as NADH.

Moreover, in an imidazole-buffered medium, most vanadate (v) can be chelated preferentially with imidazole rather than with NADH. In this case, the NADH-vanadate redox reaction (which

proceeds in other buffers within the NADH-vanadate complex<sup>1,7</sup>) is stopped and needs to be triggered by other ligands (for example, by flavines, F.V., H.D. and J.T., unpublished results).

Another possible source of discrepancy between our results and those of Erdmann et al. may have resulted from different treatment of membrane fractions with sodium iodide8. Other facts must be taken into account, such as the stability of the preparation<sup>2</sup> and the possibility of contamination of the cytoplasmic dehydrogenases, which can be attached to the membrane8.

For these reasons we believe that within the cell, the oxidation of NADH by vanadate may proceed by forming a complex without any additional support from a specific enzyme, but we do not doubt the validity of the data obtained by Erdmann et al. in their specific experimental conditions.

Note added in proof: The rapid nonenzymatic oxidation of NADH (10<sup>-3</sup> M) by vanadate (10<sup>-3</sup> M) in phosphate buffer (pH 7.0) is accompanied by the appearance of equivalent amounts of vanadyl(IV) as revealed by the ESR method (Pilař, Vyskočil, Dlouhá and Teisinger, in preparation).

#### **Matters Arising**

Matters Arising is meant as a vehicle for comment and discussion about papers that appear in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted. Neither contribution nor reply (if one is necessary) should be longer than 500 words and the briefest of replies, to the effect that a point is taken, should be considered.

#### Lower Palaeozoic oceans and Wilson cycles

ANDERTON1 has recently suggested that Iapetus (the ocean separating north-west and south-east Britain in the Lower Palaeozoic) may have opened as late as the beginning of the Cambrian. There seems to be a general concensus now that these two parts of Britain were brought together in late Silurian-early Devonian times and that an ocean between them-Iapetus-was thereby destroyed. It has been almost tacitly assumed since the early models of Wilson<sup>2</sup> and Dewey<sup>3</sup> that this ocean must have opened some time before this. Most models (including my own4) have assumed that an ocean existed between north-west and south-east Britain for a considerable period. But, from palaeomagnetic reconstructions of the late Precambrian and early Palaeozoic<sup>5,6</sup>, Iapetus was probably not a two-sided ocean comparable with the Atlantic and there therefore seems little justification for trying to narrow down the timing of opening of a non-existent ocean.

There are few reliable constraints on the relative latitudinal positions of the two sides of the Caledonides in late Pretimes. One interesting cambrian palaeomagnetic result suggests that the Baltic Shield may have lain to the southeast of Scotland in late Grenville times7. This position would make the similarities between the Scottish Dalradian and the northern Norway late Precambrian more easily understandable and the 'opening' suggested by Anderton<sup>1</sup> may be allied to the separation of the Baltic and Laurentian shields. This would be regarded as the 'opening of Iapetus' by Scandinavian geologists but is a different concept from that generally envisaged in Britain and it must be remembered that the original designation of Iapetus<sup>8</sup> was for the Svalbard-Scandinavia-Greenland segment of the Caledonides. Faunal differences between south-east Britain and Scotland thus become irrelevant to the opening of that ocean.

The position of south-east Britain in late Precambrian and early Palaeozoic times is essentially unknown, but the combination of a distinctly different Precambrian structural history between the two sides and the widely different Lower Cambrian faunas suggests that north-west and south-east Britain were not in juxtaposition at any time before the final closure of Iapetus. Palaeogeographical models<sup>5,6</sup> have all put south-east Britain at the edge of completely different continental masses from Scotland-and not on the 'other' side of a linear ocean. It is only by rotations and large scale lateral translations (along major transforms of the ocean floor<sup>6</sup>) that the two sides eventually came together at the end of the Silurian. The Iapetus Ocean thus only existed as a twosided closing ocean for probably the last part of Ordovician and Silurian times, at least in the Britain-Appalachia segment of the Caledonides.

reconstructions suggest Many completely different patterns of movement for the various sections of the southeast margin of the Caledonian orogeny. Morocco, Avalon (Newfoundland)/New England, Iberia/Brittany, England/ Wales, central Europe and Scandinavia may all have moved independently from widely separated positions on the globe to their final resting place against the more or less uniform north-west margin of Greenland-Scotland-northwest Newfoundland-Appalachia. This is fairly unlikely in that one might not expect several microcontinental fragments to collide at even approximately the same time to form the Caledonide orogeny (even allowing for the now well recognized differences in time of collision between Scandinavia and north-west England<sup>9</sup>). There is no evidence that these microcontinental fragments show any evidence of collision with each other before the final closure of The fact that Morocco, Iapetus. Avalon/New England, south-east Britain and Brittany/Iberia also show evidence of a similar late Precambrian history at the margin of a continent suggests that these fragments may have lain along one continental margin<sup>10</sup> which gave rise to the Cadomian cordilleran-type continental margin orogeny.

The sediments of the central European area of this age are marine, probably not shelf sediments, and include a considerable proportion of submarine volcanics, but again the geotectonic nature of the volcanicity and its significance are uncertain. However, it still seems likely that a late Precambrian-early Palaeozoic ocean margin lay along the line of the central European Palaeozoic massifs.

Thus the closure of Iapetus at the end of the Lower Palaeozoic seems a good example of the end of a Wilson cycle. But the late Precambrian and Cambrian history of the two sides of the closing ocean suggests that the opening phase of the Wilson cycle—the splitting apart of the continental mass-probably only affected Scandinavia and Laurentia. In this respect the suggestion<sup>11</sup> that the 560-Myr alkaline volcanic<sup>12</sup> and rift system of the North Atlantic may be an indication of the initial splitting may be correct. These volcanics and graben structures occur in Canada, South Greenland and near Oslo on the Baltic Shield, while the Carn Chuinneag granite of the Scottish Moine area, which is also an alkaline pluton 13 of this age<sup>14</sup>, may well be a Scottish equivalent of this suite. However, the suggestion that the Charnwood Forest volcanics also belong to this event, and even that it lies in a rift structure9, are not based on any real evidence. In fact all the volcanics on the south-east side which

have been suggested as remnants of the initial splitting probably belong to a volcanic arc system resultant from subduction under this continental margin9.

The whole concept of a Wilson cycleof continental splitting, ocean widening and continental closure—thus takes on a new light. Study of the closing oceans of many areas through geological time, now made possible by the palaeomagnetic and palaeogeographical compilations of Smith et al.1 and Zeigler et al.5, reveals that collisions are not between many continental fragments that had previously been even approximately adjacent, although neither goes far enough back into the Precambrian to describe the early portions of the two sides of Iapetus.

ANDERTON REPLIES-I agree with Wright about the need to reconsider the Wilson cycle and most of his points about the plate tectonic evolution of the British Isles. As I have discussed the opening of Iapetus in some detail elsewhere<sup>1</sup>, I shall just summarize my present views.

I agree that during the Precambrian, north-west and south-east Britain evolved in isolation from each other and that the late Silurian/early Devonian continental collision brought them together for the first time. However, the similarities between Laurentia and Baltica suggest that these areas were part of the same plate during the late Precambrian (although not necessarily in their post-Caledonian relative positions), that this plate split at the end of the Precambrian or in early Cambrian times to form the Iapetus Ocean and that the ocean subsequently dosed. Thus, although it does not make sense to talk about the opening of Inpetus in the restricted

context of the British Isles, it may well make sense in a broader, North Atlantic context. However, as Wright implies, the suggested opening and closing of Iapetus between Laurentia and Baltica may well be the exception in plate tectonic behaviour, and the collision of previously unrelated plates, as exemplified by the British Isles, be the rule.

of their procedures on just one or a few of these variants?

Our own unpublished observations indicate that all of a variety of tested W compound mice lack cells staining with toluidine blue in both skin and intestine. The mice tested include  $W^{sh-2}W^{sh-2}$  (ref... 8), which apart from being black-eyed whites are otherwise substantially normal. Thus the W locus seems to control 'toluidine-blue-affin' cells as well as pigment migration.

#### Spleen colony-forming cell as common precursor of tissue mast cells and granulocytes

THE demonstration by Kitamura and his colleagues1 of the origin of mast cells from CFU-S is persuasive but to us incomplete. Recipient  $W/W^v$  mice with great paucity of mast cells and CFU-S, nevertheless have stem cells which support haematopoiesis and rescue lethally irradiated mice<sup>2,3</sup>. Donated hemi-syngeneic stem cells from single splenic colonies of normal and beige mice must be few, on average of the order of 10 (ref. 4); only a minority of colonies from the tail of the skew distribution have 100 or more which may be necessary to father without mitotic exhaustion<sup>5</sup> a viable population of donated haematopoietic cells so as to compete with the host's established haematopoiesis. Kitamura et al. claim 23/106 such occasions (Table 1 of ref. 1); but their Table 2 identifies only 2/106 where erythropoiesis was demonstrable in addition to a raised population of 'mast' cells

Indeed we question whether mast cells have been demonstrated at all. They used as their criterion cells stained with toluidine blue. The 23 reported cases with whole body distribution are highly biassed by cells in spleen. It could be that these are basophil granulocytes of myeloid tissue, possibly but not necessarily equated with tissue mast cells. Note that none of the 106 animals showed mast cells in skin, which is repopulated by donor mast cells when compound W mice are repopulated with a generous supply of normal stem cells (ref. 6 and our unpublished results).

Others7 have drawn distinctions not mentioned here between skin and intestinal mast cell populations. Is it not likely that cells staining with toluidine blue are quite heterogeneous and that Kitamura et al. are observing the effects Kitamura, Y., Yokoyama, M., Matsuda, H., Ohno, T. & Mori, K. J. Nature 291, 159-160 (1981).

- 8. Lyon, M. F. & Glenister, P. Mouse News Lett. **59**, 18 (1978).

KITAMURA AND *YOKOYAMA* REPLY-We have reported that the spleen colony-forming cell is a common precursor of tissue mast cells and neutrophil granulocytes1. We used mice of two mutant genotypes in the experiment. Giant granules of  $bg^{J}/bg^{J}$  mice were used for identification of the origin of both tissue mast cells and neutrophils, and  $W/W^{v}$  mice were useful recipients because they lack tissue mast cells.

Loutit et al. have pointed out a discrepancy between the proportion of mice in which mast cells appeared and that of mice in which donor-type erythropoiesis was demonstrable. As they mentioned,  $W/W^{v}$  mice have haematopoietic stem cells but their function is apparently abnormal. Numbers of neutrophils, erythrocytes and tissue mast cells in adult  $W/W^{v}$  mice are respectively ~100, 50 and 1% of the value in congeneic +/+mice<sup>2,3</sup>. The mechanisms which determine such differentiation patterns of abnormal stem cells in  $W/W^{\circ}$  mice are unclear. However, the haematological situation in  $W/W^v$  hosts may explain the discrepancy discussed by Loutit et al. The transplanted normal stem cells might be selectively committed to tissue mast cells rather than to neutrophils or erythrocytes.

We think that the 'toluidine-blue-affin' cells counted in our experiments are true mast cells for the following reasons. (1) The cells were not only stained with toluidine blue but also contained

histamine and heparin. The histamine concentration in the forestomach4 and the skin<sup>5</sup> of  $W/W^{\circ}$  mice is ~1% the value observed in +/+ mice. Heparin is not demonstrable in the skin of  $W/W^{v}$  mice<sup>6</sup>. (2) The toluidine-blue-affin cells do not seem to be basophil leukocytes on the basis of their morphology and mode of differentiation. Typical mast cells can be differentiated from typical basophils by morphological criteria7. Most toluidineblue-affin cells which appeared in the spleen of  $W/W^{v}$  mice after transplantation of spleen colony-forming cells were typical tissue mast cells. Moreover, no typical basophils were detected in smears of the bone marrow, spleen or peripheral blood of mice of any genotypes. Basophils, as well as neutrophils and eosinophils, seem to leave haematopoietic tissues after maturation. In contrast, precursors of our toluidine-blue-affin cells proliferated in connective tissues before final differentiation is characteristic of tissue mast cells8,9

The fact that there was no increase in mast cell number detected in the skin of  $W/W^v$  mice after injection of cells from a single spleen colony may be attributable to the differential demands of mast cell differentiation between tissues. Donortype mast cells appeared in the caecum and stomach but not in the skin when bone marrow cells of  $bg^{J}/bg^{J}$  mice were injected into irradiated +/+ mice<sup>10</sup>. However, the origin of the intestinal mast cells was not different from that of skin because donor-type mast cells also appeared in the skin after local applications of methylcholanthrene to such radiation chimaeras9. Moreover, mast cells appeared in the caecum and stomach of  $5/9 W/W^{v}$  mice but in the skin of only 1/9 W/W" mice after transplantation of a small number (104) of bone marrow cells from the +/+ donors<sup>11</sup>, this mouse was also cured of anaemia<sup>11</sup>.

## Cosmology, Physics, and **Philosophy**

Recent Advances as a Core Curriculum Course

1981. Approx. 510 pages. Cloth DM 69,-; approx. US\$ 32.10 ISBN 3-540-90581-2

This treatise provides an interdisciplinary perspective establishing a common ground for science and philosophy: a perspective applicable to a variety of college courses ranging from the foundations of the exact sciences, or socio-philosophical studies in general science, to advanced topics in physical sciences (quantum mechanics, relativistic cosmology, modern astrophysics, and the physics of time anisotropies). Addressed to a wide audience, the material is organized largely into two distinct levels, one providing an indispensable core of basic knowledge for every advanced, modern student, and the second more intensive applications to be used selectively in specific fields, such as physico-philosophy and physicomathematics. In bringing this material together, and fusing it into a unified, cohesive field, the author challenges prevailing assumptions in scientific practice and methodology, calling for reeducation in such realms as the study of time, relativity, causality, large- and small-scale physics, idealism, materialism, and rationalism. Throughout, the scientist is urged to recognize and develop a philosophical foundation, while the philosopher is reminded that his results must be consistent, verifiable, and compatible with logic.

## The Foundations of Biological Theory

by E.H. Mercer, University of Hawaii

This unique book argues that biology, like physics, is subject to the natural laws of physics, but that — neither for biological or physical systems — are these laws sufficient to describe actual existing systems. It emphasizes the role of chance in both biological and physical systems, and explores in depth the possibility that evolutionary changes are generated by unpredictable chance mutations at a sub-atomic level. Discussions of the hierarchical organization of biological organisms and of free will vs. determinism shed new light on these issues.

Contents: Physics and Biology; Heat, Entropy, Information, and Evolution; Organization, Levels of Organization, and Machines; Biological Organization; The Construction of Organized Systems; Organization in the Open System, Nonequilibrium Thermodynamics; Aleatory Phenomena; The Origination of Biological Systems; Summary; Index.

## **Denitrification**

by J.W. Payne, University of Georgia

The experimental data on the four anaerobic, reductive steps that comprise bacteria denitrification are examined in this book. It presents evidence for and against the enzymatic involvement of nitric oxide in denitrification along with evidence proving that nitrous oxide is an intermediate in denitrification. It contains strategies for the management of fertilizer and irrigation, with an eye toward minimizing nitrogen losses. The book discusses the difficulties of measuring denitrification losses in field soil, and surveys current practical approaches to the use of gas chromatography, isotropic tracers and controlled-environment chambers. Numerous tables and charts illustrate significant experiments concerning the nature of denitrification and denitrifying bacteria.

## **Nosocomial Infections**

edited by R.E. Dixon, Helene Fuld Medical Center

Focuses on the significant progress made in the field over the last decade, with highlights on the determinitive role of the host, concepts of immunoincompetence, pathogens and emerging pathogens, the epidemiology of antimicrobial drug resistance, chemoprophylaxis, and environmental control. This is a state-of-the-art report that is destined to become an indispensable part of every physician's library.

## Management of Anaerobic Infections: Prevention and Treatment

by **A.T. Willis, P.H. Jones,** and **S. Reilly,** all of Public Health Laboratory, Luton, Bedfordshire

A comprehensive discussion and review of the prevention and management of anaerobic bacterial diseases including clost-ridial infections and non-clostridial anaerobic infections including post-surgical sepsis. A full bibliography is included. Series: Antimicrobial Chemotherapy Research Studies, Vol. 1 0471 28037 2 106pp July 1981 \$26.60/£9.50 Research Studies Press: A Division of John Wiley & Sons Ltd.

## Electron Microscopy in Biology, Vol. 1

edited by J.D. Griffith, University of North Carolina, Chapel Hill Discusses current techniques and biological applications of electron microscopy, serving as a unifying reference for various subdisciplines. Topics in this first volume include image processing, freeze-etching of chloroplast membranes, chromatin ultrastructure, visualization of RNA, and visualization and mapping of genes by the R-loop technique. It also includes critical interpretations of electron micrographs.

## The Sarcoplasmic Reticulum: Transport and Energy Transduction

by L. de Meis, Federal University of Rio de Janeiro

Discusses the mechanisms of Ca²+ transport and energy transduction in isolated sarcoplasmic reticulum vesicles. It raises the possibility that the sarcoplasmic reticulum might interconvert binding energy into chemical energy. The book shows that, under suitable conditions, the entire process of Ca²+ transport can be reversed and the very same ATPase involved in Ca²+ transport is able to catalyze the synthesis of ATP in a process coupled with the release of Ca²+.

## **BOOK REVIEWS**

## I and brain

## **Donald Michie**

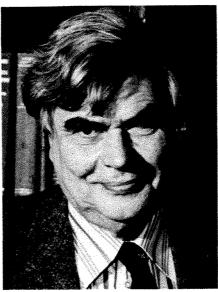

CONCERNING ways in which language limits perception, Paul Henle has observed:

It would seem then to be consistent with what we know of mental set on other grounds to assume that the world appears different to a person using one vocabulary than it would to a person using another. . . . The Navaho, for example, possess colour terms corresponding roughly to our 'white', 'red', and 'yellow' but none which are equivalent to our 'black', 'grey', 'brown', 'blue', and 'green'. They have two terms corresponding to 'black', one denoting the black of darkness, the other the black of objects such as coal. . . . As far as vocabulary is concerned they divide the spectrum into segments different from ours.

The passage is quoted in a new book by our most prominent student of the physiology and psychology of perception, who moreover brings to it an unusual insight into the science of mechanism: Richard Gregory is also a competent and highly inventive engineer.

A decade or more ago his Eye and Brain confirmed for perception what Martin Gardner's Logic Machines and Diagrams had earlier shown for deductive thought first, that analysis of brain-mediated operations prospers better on a machineoriented than a metaphysical base; and second that brilliant popularization is possible without loss of rigour. The intellectual vocabularies which Gregory brought to bear in Eye and Brain were those of neurobiology and engineering physics. Both are native to him as a scientist, and they were precisely the two which the task demanded. The new enterprise, Mind in Science, far out-demands the old, being no less than a survey from earliest times of the effects of technology upon explanatory theories in science.

The requirement for a multi-lingual intellect imposed by such a task seems aweinspiring. The book's 600 pages sweep through the origins of myths and of tools, the invention and nature of writing, of mathematics and of machines; through natural philosophy from pre-Socratic to post-Einsteinian; through early notions of biology and medicine to the origin of species and to the descent and cultural ascent of man; to the measurement and definition of intelligence, the philosophy of mind, the physiology of brain, the psychology and metaphysics of perception, and finally to language, consciousness and the nature of knowledge and truth. Interwoven through the narrative are strands of sociology, mechanics, thermodynamics, cybernetics (this last is genially labelled by Gregory's broad brush as "Artificial Mind in Science: A History of Explanations in Psychology and Physics. By Richard L. Gregory. Pp.641. ISBN UK 0-297-77825-0; ISBN US 0-521-24307-6. (Weidenfeld & Nicolson/Cambridge University Press: 1981.) £18.50, \$29.95.

Richard Gregory — a good companion

Intelligence") and of symbolic logic.

Equally breathtaking is how close Gregory comes to success. It is as though some Leonardo of the Navaho had essayed a treatise on pigments of many lands, and had almost accomplished the heroic act while still, to return to Henle, having but a single term for "grey" and "brown", and another for "blue" and "green". The mental vocabulary missing from Gregory's near-masterwork is that of computation, interpreted broadly to include the principles of modern predicate logic and the means of implementation adopted by the designers of the new generation of intelligent computing systems. In the result, whenever we follow the author to the active modelling of thought by machine, our thirst intensifies; but it is at these very points that the stream dries.

The abstract forerunner of the modern computer is A.M. Turing's startling and consequential theoretical construct, the Universal Turing Machine. One might expect this historic intellectual mechanism to figure prominently in a book with such a theme as Gregory's. It comes as a surprise to find it boiled down to "... the important notion advanced by the pioneer computer scientist at Manchester, Alan

Turing: that anything that is conceivable can be represented by a simple machine, capable of a very long string of alternative states". The "important notion" was in fact advanced in the mid-1930s when Turing was at Cambridge. When he moved at Max Newman's invitation to Manchester in September 1948 it was not to "found the Manchester computing laboratory" as stated later in this book (p.382). By that time Tom Kilburn and F.C. Williams had already achieved operation of the Manchester prototype on which they had embarked in December 1946. But more serious is the author's failure to grasp, and hence to communicate, what the whole Babbage-Turing-Kilburn-Williams-Wilkes-Eckert-Mauchly-von Neumann story was actually about.

Richard Gregory has one of the most richly furnished and dazzling minds that I have ever encountered. But for every person, there are one or two subjects which run so widdershins to the natural grain as to become subtly repellent, almost "antisubjects". For myself, however long and intently I strive, I cannot learn a foreign language. Gregory cannot learn a computer language. At Edinburgh he was briefly enticed into the attempt. But the terminology of tests and loops seemed to grate so painfully that the experiment was dropped. Here is a clue to what can make a scholar attached to historicity and precision go awry. When the anti-subject returns to mind, repellency is re-awakened and the instruments of memory are jarred.

I was captured by the dream of AI while it was yet a seed without flower or fruit: to leave Cambridge to help my colleagues Donald Michie and Christopher Longuet-Higgins to set up the Department of Machine Intelligence and Perception at Edinburgh University. Here we collaborated with the corresponding Departments at MIT and Stanford, and we built the Robot Freddy, which was one of the first to recognise objects from any point of view and to make models.

A meccano mounting of a TV camera on two small motor-driven wheels had indeed been used by Barrow and Popplestone (see their subsequent 1971 paper in *Machine Intelligence* 6) for their own preliminary skirmish with the vision problem before Gregory's departure to Bristol in September 1970. But the robot to which he must surely be referring was then still at the planning stage, to be completed, and its computer-based accomplishments demon-

strated, 2½ years later. The team which saw the Freddy project through consisted of A.P. Ambler, H.G. Barrow, C.M. Brown, R.M. Burstall and R.J. Popplestone (see their paper in *Artificial Intelligence* Summer 1975); and on the hardware side S. Salter (mechanical engineering) and Gregan Crawford (electronics).

It should also be recalled that the founding giants of AI, men such as Samuel, Simon, Newell, McCarthy, Minsky, Robinson and Rosen had been labouring to set the cornerstones some ten years before Gregory was captured by his dream of flower and fruit. But the bold literary approximation sometimes economically conveys a deeper truth. Before he left Edinburgh Gregory taught us that if a robot is to see, then its programmers must enable it to reconstruct its percepts, as does the human being, from a stored inventory of how the components of familiar objects and scenes normally look. This Helmholtzian doctrine is a cliché of computer vision today. In those days it was not, and the launching orientation was derived, to speak for myself, in powerful measure from Gregory.

From time to time in the book this gift flashes forth to astonish, illuminate and (occasionally) to infuriate. It is human to be irked by an inspired guide who against overwhelming odds brings one to the right door, only to signal by tell-tale fumblings that he lacks the door key. But is it rational to be irked? Who else could have piloted one thus far? Moreover one is perfectly free to thank him and look for a key-owner or a locksmith. Gregory has seen from afar that the instruments of thought-automation are the "tools", "materials" and "processes" of a new industry, the technology of human knowledge. On approaching closer, his expertise gives out, just where that of the new race of knowledge engineers begins. The important thing, however, is that his insight is correct.

The book's pivotal chapter, "The Nature and Nurture of Intelligence", will stir profitable thought in laboratories where man-machine synthesis of prototype knowledge systems is making precise what Gregory's mind's eye has spied. As with the book as a whole, the chapter tells everything about the philosophy of AI, nothing of the method.

It also tells on every page a very great deal about its author. From this comes many flaws, but much charm. One of the joys of the scientific life is to drop for a while the customary pendantries in exchange for good companionship. Mind in Science offers sustenance of just this kind. Possibly some scientific or philosophical people may abstain from its pages. They must be warned that they will have to continue their journey more poorly supplied than need have been the case.

Donald Michie is Professor of Machine Intelligence in the University of Edinburgh.

## Cell transformation: a missed opportunity

Daniel Rifkin

Neoplastic and Normal Cells in Culture. Developmental and Cell Biology, 8. By J.M. Vasiliev and I.M. Gelfand. Pp.372. ISBN 0-521-23149-3. (Cambridge University Press: 1981.) £40, \$79.50.

THE enormous increase of interest over the past ten years in the molecular biology of tumour viruses, as well as in the physiology of cultured cells, has created an extensive literature on the properties of normal and transformed cells, and on the relationships of these properties to the cellular phenotype. There is no book currently available which brings together the large body of information accumulated in this area. Thus, it was with pleasure that I began Vasiliev and Gelfand's book Neoplastic and Normal Cells in Culture. The aim of the authors is "to describe and discuss comparative characteristics of the interactions of normal and neoplastic cells with their environment in cell cultures". The book, then, would appear to be the perfect vehicle for a synthesis of data on those properties of neoplastic cells responsible for their altered growth, their invasive behaviour and their metastatic potential, specifically as measured by in vitro criteria.

The book is divided into four parts. Part 1, an introduction, is subdivided into two sections: the first covers the general properties of neoplastic cells, especially growth, and the second deals with neoplastic transformation in culture by a variety of agents. The second part of the book, "Morphogenesis in 'Normal and Transformed Cultures'," is concerned with cellular structures and their function in relation to morphogenesis. This includes the movement of normal fibroblasts and epithelial cells in relation to their morphology, the locomotion and morphology of tumour cells, and specific biochemical or cytological processes whose alteration may be responsible for the difference between normal and transformed cells. Part 3 deals with growth regulation in normal and transformed cells, concentrating on the anchorage, density and soluble factor controls of cell division, and the interactions of these phenomena. The book concludes with a general discussion based on a comparison of in vitro and in vivo malignant cells as well as the interrelationships of transformation properties.

Within the scope of the authors' aims, the book is filled with interesting references and intriguing observations. The authors present a number of thoughtful conclusions and certainly point out certain ambiguities in the data from different laboratories.

However, the book has two serious deficiencies. The first of these is the cursory discussion of the possible significance of

cell-matrix interactions in determining the cellular phenotype. The possible influences of fibronectin, collagen and proteoglycans on cell behaviour are given little more than two paragraphs. This is a rather exciting area of current experimentation but it is presented essentially as an adjunct to the more morphological research. This, in fact, is the second shortcoming of the book - the emphasis on morphological aspects to the virtual exclusion of biochemical analysis. An enormous variety of cellular phenomena is described, but only in a few instances is there any discussion of the possible molecular basis for these phenomena.

But perhaps the most disappointing aspect of the book is its blandness. All of the information presented receives much the same degree of emphasis and enthusiasm. The authors rarely indicate a preference for one interpretation versus another, nor do they ever criticize omissions in the data, the lack of proper controls or internal inconsistencies. This is not a critical presentation of the data. It was rather disheartening to read through a book concerned with an area of such excitement and find only a compendium of facts. The failure to create any larger order out of the enormous amount of information available must be counted as a missed opportunity.

Daniel Rifkin is an Associate Professor of Cell Biology at New York University Medical School.

## Resources on a plate

Frederick J. Sawkins

Economic Geology and Geotectonics. Edited by D.H. Tarling. Pp.213. ISBN UK 0-632-00738-9/ISBN US 0-470-27145-0. (Blackwell Scientific/Halsted Press: 1981.) £15, \$54.95.

THE possible relationships of resources of various kinds to geotectonics is a subject that is attracting considerable attention nowadays, and this volume was apparently conceived with the object of providing an introduction to anyone — undergraduates, postgraduates and even seasoned researchers — with an interest in the field. Sadly, the book failed to live up to my initial expectations. It contains nine chapters by eight contributing authors, and opens with an introduction to the general theory and operation of plate tectonics. Although somewhat sparsely illustrated, this account provides a competent

## MALTING AND BREWING SCIENCE

Second Edition

Volume I: Malt and Sweet Wort

JS Hough, DE Briggs, R Stevens and TW Young

A comprehensive account of the biological, biochemical and chemical aspects of malting and brewing. This fully revised second edition is published in two parts: Volume 2: Hopped Wort and Beer, will be published during 1982. An essential reference source for all scientists in brewing and related industries.

## CELL DEATH IN BIOLOGY AND PATHOLOGY

Edited by I D Bowen and R A Lockshin

A survey of current research on the occurrence and mechanisms of accidental, induced and genetically-programmed cell death. Chapters by leading researchers cover aspects of cell death in embryogensis, metamorphosis, immunology and pathology. This book will be an important source of reference for workers in all areas of cell biology.

November 1981, 450 pp Hb 0 412 16010 2 £30.00 \$65.00

## SOILS AND THE ENVIRONMENT

A guide to soil surveys and their applications

Gerald W Olson

Provides a comprehensive account of soil survey interpretations for readers in countries at all stages of economic and agricultural development. This book will be used by students and teachers of agriculture, the earth sciences, and engineering, as well as by professionals concerned with rural planning and resource management.

December 1981, 192 pp Hb 0 412 23750 4 £15.00 Pb 0 412 23760 1 £6.50 \$16.95

## THE AMERICAN COCKROACH

Edited by W J Bell and K G Adiyodi

An integrated account of the biology of the American Cockroach (*Periplaneta americana*) which summarizes our current knowledge on this species. Essential reading for all scientists who work with this animal in the laboratory or who are involved in pest control.

## THE LABORATORY COCKROACH

WIBe

An extensively illustrated laboratory manual for students and staff in zoology and entomology which gives methods and materials for many experiments using cockroaches.

January 1982, 176 pp Pb (spiral bound) 0 412 23990 6 £6.95

## WOODLAND CONSERVATION AND MANAGEMENT

George Peterken

This book summarises the development of today's woodland and shows how the demands of forestry and conservation can be integrated without coming into direct conflict with each other. An authoritative source of information for all working in forestry, conservation, landscape planning and similar areas.

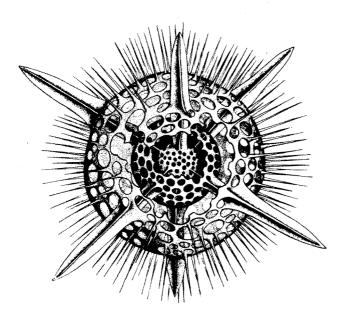

December 1981, 336 pp Hb 0 412 12820 9 £25.00 \$49.95

733 Third Avenue, New York, NY 10017

## A close look at Springer MICROBIOLOGY

## The Prokaryotes

A Handbook on Habitats, Isolation and Identification of Bacteria

Editors: M. P. STARR, H. STOLP, H. G. TRÜPER, A. BALOWS, H. G. SCHLEGEL

1981. Approx. 433 figures. Approx. 2625 pages (In 2 parts, not available separately) Cloth DM 880-; approx. US \$ 409.70 ISBN 3-540-08871-7

The Prokaryotes, containing 169 contributions by 182 of the world's leading researchers in microbiology, is an encyclopedic treatment of all practical information on bacteria. Six introductory essays discuss the general characteristics of prokaryotes.

The chapters that follow explicitly describe each bacterial group's:

- habitats their diversity in nature, normal and abnormal sites where they may be found and field procedures for collecting and analyzing samples
- enrichment and isolation clearly explained techniques for initiating and promoting culture growth and isolation of culture colonies
- identification their morphologies are meticulously defined and illustrated, and differentiated morphotypes within each group are compared and contrasted
- clinical aspects where applicable, clinically significant characteristics are given. Approximately 40% of the contents have medical application, including information on exotic pathogenic organisms rarely discussed anywhere but in the most specialized research journals
- history both natural history and research history
- references fully annotated per chapter, a guide to the primary research and secondary sources of information

K. HORIKOSHI, T. AKIBA

## Alkalophilic Microorganisms

A New Microbial World

1981. Approx. 270 pages Cloth DM 98,-; approx. US \$ 45.70 ISBN 3-540-10924-2

Distribution rigths for Japan: Japan Scientific Societies Press, Tokyo

From the Contents: Introduction. – Isolation, Classification, Growth Conditions, and Physiology of Alkalophilic Microorganisms. – Molecular Biology of Alkalophilic Bacteria. – Enzymes Produced by Alkalophilic Microorganisms. – Industrial Applications. – Future Scope.

H. IIZUKA, A. NAITO

## Microbial Conversion of Steroids and Alkaloids

1981. XI, 396 pages Cloth DM 98,-; approx. US \$ 45.70 ISBN 3-540-10794-0

Distribution rights for Japan: University of Tokyo Press, Tokyo

From the Contents: Microbial Conversion of Steroid Hormones, Bile Acids, Sterols, Sapogenins, Cardenolides, Alkaloids. – Conversion of Steroid Hormones and Cardenolides by Plant Cell Suspension Culture. – Author, Microorganism, Plant, and Substance Index.

## **Beta-Lactam Antibiotics**

Editor: S.MITSUHASHI

1981. XII, 325 pages Cloth DM 98,-; approx. US \$ 45.70 ISBN 3-540-10921-8

Distribution rights for Japan: Japan Scientific Societies Press, Tokyo

Contents: History. - Epidemiology and Genetics of Resistance. - Biochemical Mechanisms of Resistance. -Structure and Function Relationships. - Mode of Action. -Pharmacokinetics. - Allergy. - Name Index. - Subject Index. - Material Index.

## **Biosynthesis**

Editor: J. W. CORCORAN

1981. 164 figures. XII, 380 pages (Antibiotics, Volume 4) Cloth DM 198,-; approx. US \$ 92.20 ISBN 3-540-10186-1

For more than a decade, the Springer *Antibiotics* series has been a reliable source of precise information on the mode of action and biosynthesis of these important drugs. In this new addition to the series, information on biosynthesis contained in volume II is brought up-to-date, reflecting current knowledge of the major antibiotics. The material is organized according to the type and complexity of the biosynthetic process in question.

Written by internationally recognized specialists, Antibiotics IV will prove an invaluable reference for researchers in this fascinating field. Students will also find it an aid to their understanding of the biochemical processes involved in the biosyntesis of antibiotics.

## Springer Series in Microbiology

## **Basidium and Basidiocarp**

**Evolution, Cytology, Function and Development** 

Editors: K. WELLS, E.K. WELLS With contributions by numerous experts

1982. Approx: 117 figures, Approx. 210 pages Cloth DM 89,-; approx. US \$ 41.50 ISBN 3-540-90631-2

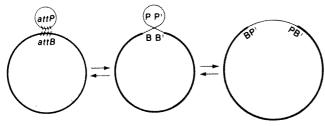

Extensively illustrated, Basidium and Basidiocarp is a comprehensive review of recent studies into the class of basidiomycetes. They are examined from the taxonomic, cytologic, molecular biological, physiologic, and biochemical points of view in order to provide a broad picture of modern findings and the experimental procedures underlying them.

## A.R. MAGGENTI

## **General Nematology**

1981. 135 figures. Approx. 385 pages Cloth DM 78,-; approx. US \$ 36.40 ISBN 3-540-90588-X

General Nematology is a comprehensive monograph designed to acquaint the reader with the biology and morphology of all forms of nematodes. Setting aside the traditional separation between plant and animal nematologists, the author treats the field as unified discipline, illustrating the evolutionary development, the similarities and interrelationships among plant, insect and vertebrate parasites and their connection with free living counterparts.

E. A. BIRGE

## **Bacterial** and **Bacteriophage Genetics**

An Introduction

1981. 111 figures. XVI, 359 pages Cloth DM 54,-; approx. US \$ 25.20 ISBN 3-540-90504-9

Here is an ideal introduction to the genetics of bacteria and bacteriophages. The book provides extensive coverage of the major genetic systems of a large number of organisms. Recent developments in DNA splicing technology and transposable elements are stressed. The emphasis is on genetics, and the biochemical and molecular biological background.

This thoroughly documented and illustrated text will fill the needs of students taking courses in bacterical genetics and will also provide a solid base of knowlege for embarking in research.

## **Ascomycete Systematics**

The Luttrellian Concept

Editor: D. R. REYNOLDS

With contributions by numerous experts

1981. 122 figures. IX, 242 pages Cloth DM 79,-; approx. US \$ 36.80 ISBN 3-540-90488-3

Ascomycete Systematics assesses recent progress with the Luttrellian concept and application of this concept to fungal groups where different taxonomic systems have traditionally been used. An extensive review of the literature of the last three decades is included.

## G. GOTTSCHALK

## **Bacterial Metabolism**

1979. 161 figures, 41 tables. XI, 281 pages Cloth DM 43,-; approx. US \$ 20.10 ISBN 3-540-90308-9

"... is the best concise treatment of the subject available. The text is clear and well illustrated with metabolic schemes and much tabulated information... Gottschalk's Bacterial Metabolism is excellent and I will be surprised if it is not extremely popular amongst students and teachers of microbiology and biochemistry for a very long time."

"... The book is a pleasure to read because the author presents a logical approach... This textbook is compact and filled with information and yet is simple and easy to read. It successfully combines the detailed knowledge of E. coli metabolism and the diverse metabolic activities of other microorganisms in a straightforward, basic treatment ASM News of the subject."

T.D. BROCK

## Thermophilic Microorganisms and Life at High Temperatures

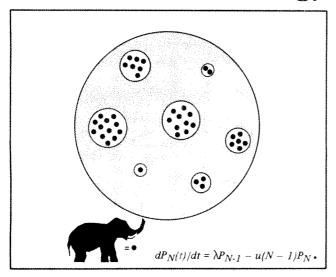

1978. 195 figures, 69 tables. XI, 465 pages Cloth DM 59,-; approx. US \$ 27.50 ISBN 3-540-90309-7

- The book stamps a record of personal achievement ...it includes valuable unpublished observations, suggests areas for future research approaches and improvised techniques that proved useful where conventional Nature methods could not work or were urravailable."
- ... It is ... the best single compilation... The book is well laid out and organized, with a good balance among text, tables, photos, and graphs, as well as a splendid collection of references in the field. My reaction, as I closed the back cover, was 'Bravo Brock'." Bio Science

Circle No.36 on Reader Enquiry Card.

The following three chapters deal with the formation, migration and accumulation of petroleum. Much of the material is a duplication of that to be found in any petroleum geology text. Plate tectonics is certainly dealt with in terms of basin development, but in view of the volume's title and its stated goals, this important subject deserved a more penetrating analysis and further fleshing-out with specific examples. Chapter 5 provides the reader with an overview of coal geology; again, much of the material is standard textbook stuff, and the chapter contains only half a page of general comments regarding possible plate tectonic controls of coal-generating environments.

The remainder of the book covers the relationships of metal deposits to plate tectonics. The chapter dealing with metal deposits formed at spreading ridges is well done and covers podiform chromite and Cyprus-type massive sulphide deposits. However, the association of ore deposits with subduction-related environments is covered in a mere seven pages of text, plus four illustrations; as a result of this brevity, many important types of deposits in subduction-related arcs are ignored, as are most of the more recent insights into arcmetal deposit relationships such as interarc rifting.

The contribution on the origins of ore deposits in sedimentary rocks is certainly of adequate length and contains a good deal of information, although the writing is somewhat laboured. I was also confused by the author's lack of conviction on certain points. For example, less than a page after a statement that the relationship between "secondary sedimentary ores and some sort of growth faulting is so common as to be almost a requirement", the suggestion that rifting is active during mineralization is questioned.

The final chapter considers the significance of palaeoclimatic factors on resources and offers some general conclusions. It touches briefly on a host of varied topics, but contains one or two startling misconceptions, for example the suggestion that the copper-sulphide deposits of Kennecott, Alaska, have a detrital orgin.

The volume contains 64 figures, many of them rather simple sketches, and only a single table. There are also a number of text citations missing in the references.

Overall, one is left with the impression of a somewhat hastily assembled volume which falls short of its claim to "provide an integrated introduction to the subject of economic geology".

Frederick J. Sawkins is a Professor in the Department of Geology and Geophysics at the University of Minnesota.

## Solving big problems on big computers

F. James

Computer Simulation Using Particles. By Roger W. Hockney and James W. Eastwood. Pp.540. ISBN 0-07-029108-X. (McGraw-Hill: 1981.) \$49.50, £27.50.

It is a pleasure, in these days of makeshift books on computing and simulation, to come across a thoroughly coherent work painstakingly prepared by recognized experts in the field.

The authors address themselves to one of the three general approaches to the study of systems (liquids, galaxies, plasmas and so on) governed by known differential equations. The other two approaches, finite elements and finite differences, are already well covered in the literature, whereas direct simulation by following constituent "particles" of the system, although in many ways more interesting mathematically, has largely been ignored except in research papers. To say that this book fills the gap is something of an understatement.

The orientation of the book is truly that of computational physics (or, as the authors prefer, computational science). It is not just a physics book with a chapter on FORTRAN at the end. Although the subject is problems arising in physics and related areas, suitability to computation is the overriding criterion for all of the material presented; no model or technique is suggested which has not been used in actual computations, more often than not by the authors themselves.

Considerable attention is paid even to programming methodology, including a rather complete account of the OLYMPUS programming system. Such a chapter could, of course, be grafted onto any book, but it finds a natural place in this work where the coverage of fundamental properties of algorithms includes not only their theoretical convergence rates, stability and such, but also actual computer time and storage requirements, arithmetic precision requirements and sometimes suitability to particular computer architectures. The usefulness of this aspect could have been enhanced still further by including a table of comparison of different computers' performance, since of the computers most often cited (IBM 7090, 360/91 and 360/195, CDC 6600 and 7600, ILLIACIV, CRAY-1) most are rare birds, technologically obsolescent or both, and, apart from the CRAY, are unlikely to be commonly available in a few years' time.

Physicists will appreciate the authors' basic approach, the mathematical notation

Volume III of *The Northwest European Pollen Flora* has been published by Elsevier Scientific. Containing detailed studies of the pollen morphology of a further eight families, the book costs Dfl.110, \$53.75.

and the vocabulary. The reader is encouraged to consider the problems in their physical context, not just as mathematical abstractions. The importance of physical insight in the choice of mathematical methods is brought out clearly. In addition, the interdisciplinary nature of the work should make it especially interesting, for example, to an astronomer who can see the relationships between problems arising in the study of the orbits of galaxies and in the design of transistors.

The style of the book is characterized by clarity and simplicity, the hallmarks of authors who have something of substance to say and possess a complete grasp of their subject. The quality of the printing, the pleasant layout of text and, especially, the numerous and helpful illustrations (many computer-produced, of course) all contribute towards making the book a real pleasure to read. It is a first-rate reference book which will be indispensable to workers in the field, and it will certainly find its place as a textbook for advanced courses in both computer science and physics, as well as intermediate fields.

Frederick James is a staff physicist in the Data Handling Division of CERN, and a past chairman of the Computational Physics Group of the European Physical Society.

## $\overline{P} = s$ . exp (E/kT): common ground in thermal physics

G.F.J. Garlick

Analysis of Thermally Stimulated Processes. By R. Chen and Y. Kirsh. Pp.361. ISBN 0-08-022930-1. (Pergamon: 1981.) \$60, £25.

WHAT might there be in common among such apparently diverse experimental operations as the thermal stimulation of luminescence or current on the one hand, and thermogravimetry or differential thermal analysis on the other? Add to these other processes measured in, for example, thermal annealing, evolved gas analysis, thermoremanent magnetism, thermal desorption, dilatometry and thermally induced creep, and there is the subject matter of the present text.

In their preface, the authors themselves make the comment that the book could look like a "marriage of convenience". However, there is more connection between the effects than that they each involve a change in some measurable physical parameter when a material sample is warmed up. The more subtle factor common to them all is the theoretical expression for the probability of the effect, which is the familiar Arrhenius exponential function  $P = s. \exp(E/kT)$ , where s is often known as the "frequency constant", E is the energy needed to effect the change in parameter, k is Boltzmann's constant and T the absolute temperature. The major problems of developing theory to correlate with any of them are not about this function but about the kinetics which determine what happens later. For instance, will an escaping electron recombine with its original location to give, for example, luminescence, or will it be retrapped?

A large part of the book is taken up with these kinetic variations and the reader interested in thermogravimetry or differential thermal analysis may find that his interests are somewhat overwhelmed by extensive treatments of thermally stimulated luminescence and conductivity. The volume will certainly not replace the many treatises on thermogravimetry or differential thermal analysis and other specific techniques to which the users of the associated, sophisticated equipment now turn. However, there is always the possibility that by reading of the existence of a wider range of thermally stimulated effects ideas may be transferred between the disciplines. In this sense the text will be very useful.

With the major concern of the authors being thermally stimulated electronic processes in insulators and semiconductors, there is a fairly exhaustive coverage of the theory and practice of studying "deep" levels in such solids. There are, however, some omissions and some inaccuracies. On a historical note, more credit should have been given to

Urbach for his quantitative assessment of thermoluminescence in 1930 which preceded that of Randall and Wilkins by many years. On the matter of retrapping the authors do not, in drawing examples from the literature, bring out the stillpuzzling case of zinc sulphide phosphors, where luminescence and conductivity can be co-explored to determine detailed mechanisms. In 1948 Wilkins and I (Nature 161, 565-566) showed that retrapping of thermally released electrons was very small even when empty traps outnumbered empty recombination centres by more than 1000:1. In another instance, when reviewing photon-induced transfer of carriers between trapping states, the enormous effect found in infrared-stimulable zinc sulphides by myself and Mason (J. Electrochem. Soc. 96, 90-113; 1949) is not referred to. These are important examples because they indicate ways in which retrapping can be examined in an important group of high band gap solids.

In spite of the problems of using thermally stimulated processes to obtain

accurate values of trap energies and crosssections, the recent development of DLTS (deep level transient spectroscopy) as a steady state method of thermal stimulation would appear to offer a breakthrough for determination of these parameters in device semiconductors such as silicon and gallium arsenide. It is a pity that some of the elegant examples of trap distributions obtained by this method were not included in the text.

There is no doubt that this book will be attractive to particular groups of readers who, like myself, have specific interests in carrier trapping and related processes in insulators and semiconductors. It is well referenced and has a critical approach to the use and interpretation of thermal stimulation methods. Whether its attempt to coordinate analysis of the many different thermally stimulated effects will appeal to a wider readership is less sure.

G.F.J. Garlick is a consultant specializing in the fields of luminescence and electronic processes in semiconductors.

## Developments in theorists' views of ecology

Richard Law

Theoretical Ecology: Principles and Applications, 2nd Edn. Edited by Robert M. May. Pp.489. ISBN hbk 0-632-00768-0; ISBN pbk 0-632-00762-1. (Blackwell Scientific/Sinauer Associates: 1981.) Hbk £20, \$42.75; pbk £10.50, \$23.95.

THEORETICAL ecology is a fast growing subject due, in large measure, to the stimulus of R.M. May and his associates; it is pleasing, therefore, that they should take the time to produce a new edition of their standard work (first published in 1976).

While retaining the same overall theme of developing a theoretical perspective from which to view the living world, the new edition contains some substantial changes. Several chapters have been modified in the light of recent work - most notably that on patterns in multi-species communities, which now considers intriguing questions such as how many trophic levels should exist and how theories about community stability and complexity can be tested. Several other chapters have been rewritten by new authors; in particular, that on plant-herbivore systems has been improved by taking greater account of herbivory in the real world. However other chapters that would have benefited from revision remain unchanged. For example, "Island Biogeography and the Design of Nature Reserves" hardly does justice to the promise of its title, design principles for nature reserves being relegated to a few paragraphs at the end. No mention is made of recent work in this area and of the debate that has come to surround the whole subject.

There are two welcome additions to the book. The first is a survey of the new kind of population dynamics that is emerging from studies of plants, in which individuals, rather than growing to a fixed size, may continue to grow indefinitely by the production of modular units of construction. The second, dealing with the economics of biological resources, follows an elegant path from ecological theory to practical questions of optimal harvesting and the regulation of fisheries.

The book does not attempt to give a comprehensive coverage of theoretical ecology — for example, the reader will search in vain for an adequate account of the dynamics of populations with age distributions or of the effects of genetic variability in ecological parameters. But any shortcomings are greatly outweighed by its merits; it is a lucid and up-to-date introduction to the contributions of R.M. May and his associates to theoretical ecology, and it deserves to be widely read by all those with an interest in the subject.

Richard Law is a Lecturer in the Botany Department at Sheffield University.

## ATTOUT CEME TS

## **Awards**

Aaron Klug (co-director of the Division of Structural Studies of the Medical Research Council's Laboratory of Molecular Biology at Cambridge University) is the winner of Columbia University's 1981 Louisa Gross Horwitz Prize for outstanding research in biology or biochemistry.

**Dr Adolf Schallamach** is the recipient of the Charles Goodyear Medal for 1982 for his contribution to the science and technology of rubber.

**Dr Waldo L. Semon**, inventor and holder of the basic patents for polyvinyl chloride (PVC), has been selected as the 1981 "Inventor of the Year" by the New York Patent Law Association.

**Prof. J. Michael Bishop**, (University of California, San Francisco) has been presented with the first Association of American Medical Colleges Award for Distinguished Research in Biomedical Sciences.

Candidates of international stature are sought for the 1982 Lita Annenberg Hazen Awards for Excellence in Clinical Research. The Award Committee will select a physician-investigator or team, who will be awarded \$50,000 (tax-free). An additional \$50,000 will be provided for the support, for up to three years, of a Research Fellow or Fellows whom the Award winner will select as associates. Nominations until 15 February 1982: to Myrna Turkeiwitz, Office of the Dean, Mount Sinai School of Medicine, One Gustave L. Levy Place, New York, New York 10029, USA.

The World Academy of Art and Sciences invites anyone interested in the Social Implications of Advances in Microbiology to nominate persons whose work may merit the II Stuart Mudd Awards to: Prof. Román de Vicente, Consejo Superior de Investigaciones Científicas, Joaquín Costa 32, Madrid — 6, Spain.

The Beilby Awards are made to British investigators in recognition of original work, which has been carried out continuously over a period of years and should have involved scientific principles in any field related to chemical engineering, fuel technology or metallurgy. The Awards are intended to encourage men and women, normally under the age of 40. Applications by 31 December 1981 to: The Convener of the Administrators, Sir George Beilby Memorial Fund, The Royal Society of Chemistry, Burlington House, London W1, UK.

The Meldola Medal will be made in 1982 to the chemist who, being a British subject and under 30 years of age at 31 December 1981, shows the most promise as indicated by his or her published chemical work brought to the notice of the Council of the Royal Society of Chemistry before 31 December 1981. Applications to: The President, The Royal Society of Chemistry, Burlington House, London W1, UK.

## **Appointments**

Dr Max Siegel, adjunct professor of psychology at Florida Atlantic University, has been elected president-elect of the American Psychological Association (APA), effective January 1982. He will become president in January 1983.

**Prof. I.L. Dillamore,** Professor of Metallurgy and Dean of the Faculty of Engineering at the University of Aston, Birmingham, has been appointed Director of Inco Limited's European Research and Development Centre in Birmingham.

Charles Alexander McDowell, has been appointed university professor of The University of British Columbia, in recognition of his contributions to chemical sciences and to the university.

**Barry Raleigh**, succeeds Neil D. Opdyke as director of Columbia University's Lamont-Doherty Geological Observatory.

## Meetings

1 December, Chemical Neurotransmission Yesterday and Today, London (Miss J. Holman, The Ciba Foundation, 41 Portland Place, London W1, UK).

1-2 December, An Understanding of Water Losses, London (The Institution of Water Engineers and Scientists, 6-8 Sackville St, Piccadilly, London W1, UK).

3 December, Electronics and the Future of Money, London (IEETE, 2 Savoy Hill, London WC2, UK).

7 December, **Digital Communications**, London (IEETE, 2 Savoy Hill, London WC2, UK).

8 December, Flood Control and Damage, London (Miss F. Spindlove, Oyez IBC Ltd, Norwich House, 11-13 Norwich St, London EC4, UK).

8 December, Transport of Membrane Proteins through the Golgi Complex, London (ICRF, Lincoln's Inn Fields, London WC2, UK).

10 December, GMP-Registration Interface, London (Dr T. Turner, Hoechst UK Ltd, Hoechst House, Salisbury Rd, Hounslow Middlesex, UK).

11 December, The Assessment of Lung Damage, Oxford (Mr S.R. Moores, AERE, Harwell, Oxon, UK).

14 December, Clinical Applications of Monoclonal Antibodies, Edinburgh (The Royal Society of Edinburgh, 22,24 George St, Edinburgh, UK).

14 December, The Structure and Function of Immunoglobulin Genes, London (Dr C. Spry, Royal Postgraduate Medical School, Du Cane Rd, Løndon W12, UK).

15 December, Some Newer Methods for the Production of Carbon-Carbon Bonds, London (Mr S. Langer, The Royal Society of Chemistry, Burlington House, Piccadilly, London W1, UK).

3-8 January 1982, AAAS National Meeting, Washington DC (AAAS-Dept R 1515 Massachusetts Ave, NW, Washington DC 20005, USA).

7 January, Space Exploration of Major Planets, London (IEETE, 2 Savoy Hill, London WC2, UK).

8 January, The Inaugral Meeting of the UK Molecular Graphics Group, Leeds (Dr A.J. Morffew, IBM UK Scientific Centre, St Clement St, Winchester, Hampshire, UK).

11 January, Dosimetry in Diagnostic Radiology, London (Mr D.W. Field, Hospital Physicists Association, 47 Belgrave Square, London SW1, UK).

13 January, Dry Etching, London (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).

14 January, Waste Materials in Concrete, Slough (Cement and Concrete Association, Conference and Training Centre, Fulmer Grange, Fulmer, Slough, UK).

13-15 January, Immunoglobulin D: Structure and Function, New York (The New York Academy of Sciences, 2 East 63rd St, New York, New York 10021, USA).

15 January, Fast Neutrons, London (The British Institute of Radiology, 36 Portland Place, London W1, UK).

27 January, Power Semiconductor Devices, London (The Meetings Officer, The Institute of Physics, 47 Belgrave Square, London SW1, UK).

12-13 February, Appropriate Medicine, London (London Medical Group, Tavistock House North, Tavistock Square, London WC1, UK).

17-19 February, Cell Proliferation, Cancer and Cancer Therapy, New York (The New York Academy of Sciences, 2 East 63rd St, New York, New York 10021, USA).

18 February, Advances in Cardiovascular Imaging, London (The British Institute of Radiology, 36 Portland Place, London W1, UK).

19 February, The Future in Radiology, London (The British Institute of Radiology, 36 Portland Place, London W1, UK).

22-24 February, Effective Management Techniques for Engineers and Scientists, Amsterdam (The Center for Professional Advancement, Postbus 19865, 1000 GW Amsterdam, Netherlands).

## BRL® PRODUCT REVIEW

Bethesda Research Laboratories, Inc. P.O. Box 6009 Gaithersburg, MD 20877
BRL GmbH Offenbacher Strasse 113 6078 Neu Isenburg West Germany
BRL Bethesda Research Laboratories (UK) Ltd.P.O. Box 145 Science Park Cambridge England CB4 4BE

## DNA Polymerase I Lyphozyme™ (E. coli)

BRL announces the availability of the first in a line of freeze-dried modifying enzymes, DNA Polymerase I (E. coli). Because of their intrinsically labile character, both restriction endonucleases and DNA modifying enzymes have a finite lifetime, and require special shipping and storage conditions. For more than two years, BRL has made available lyophilized restriction enzymes (Lyphozyme'") and continues to expand the enzymes made available in this convenient, stable form. As the first freeze-dried modifying enzyme, DNA Polymerase I is an important addition to the line of products already available from BRL. Each lot of DNA Polymerase I is assayed for contaminating endo- and exonuclease activity and qualified for use in nick translation protocols.

Circle No. 14 on Reader Inquiry Card.

## HYBRI•DOT\*\*

BRL has designed a 96-well manifold that simplifies scale-up of the sensitive "dot hybridization" procedure for detection of specific DNA and RNA sequences. In this procedure, as little as one picogram of a specific nucleic acid sequence, bound to nitrocellulose as a small spot, can be detected using <sup>32</sup>P-labeled probe ( $\sim 10^8 \,$ dpm/ $\mu$ g). Dot hybridization has been used to detect viral DNA in lymphocytes and in serum.

The 3 mm diameter sample wells of the HYBRI•DOT™ system are arranged to precisely match the array of a standard 96-well microtitration plate. This simplifies and accelerates procedures such as the large-scale screening of bacterial colonies for recombinant plasmids.

Circle No. 47 on Reader Inquiry Card.

## AMV Reverse Transcriptase

BRL is pleased to make available reverse transcriptase (RT) from the avian myeloblastosis virus (AMV). BRL qualifies each lot of AMV RT for its ability to synthesize full-length cDNA copies of rabbit reticulocyte globin mRNA in the presence of an oligo (dT) primer. At least 80% of these transcripts must be full-length copies. BRL is the only commercial supplier to qualify AMV RT for transcription of natural mRNA's into cDNA's.

Circle No. 48 on Reader Inquiry Card.

## BRL® 3'End Labeling System

BRL is now pleased to make available the BRL® 3' End Labeling System. Using terminal deoxynucleotide transferase (TdT), BRL provides complete instructions and reagents for labeling DNA with either radioactive cordycepin triphosphate (supplied by the investigator) for subsequent Maxam-Gilbert sequencing reactions or with deoxynucleotides for tailing DNA for the purpose of cloning double stranded cDNA.

Along with complete instructions, the BRL® 3' End Labeling System contains TdT, deoxynucleotide triphosphates, buffers and a test DNA.

Circle No. 49 on Reader Inquiry Card.

## 5' Terminus Labeling System

The convenience of high quality tested reagents for labeling the 5' terminus of either DNA or RNA is now available from BRL. The BRL® 5' Terminus Labeling System is composed of T4 polynucleotide kinase, buffers and a protocol for either an exchange or forward reaction. Using the BRL® System, 5 x 10<sup>5</sup> cpm/pmol and 1.5 x 10<sup>6</sup> cpm/pmol can be incorporated into a 5' extended DNA terminus by exchange and direct reactions, respectively.

Circle No. 50 on Reader Inquiry Card.

## Lambda In Vitro Packaging System

BRL is now pleased to make available the Lambda In Vitro Packaging System. Based on the procedure developed by Enquist and Sternberg, the BRL® In Vitro Packaging System can be used in conjunction with λ1059 (BRL #5366), λgt WES•λBDNA (BRL #5267) or λ Charon 28 (BRL #5352).

With the BRL® In Vitro Packaging System, packaging efficiencies of up to  $4 \times 10^7$  pfu/ $\mu$ g wild type  $\lambda$  DNA are routinely obtained.

Circle No. 51 on Reader Inquiry Card.

## Lambda 1059

BRL now offers a new "phasmid" cloning vector,  $\lambda$  1059. This vector, developed by Jonathan Karn and coworkers allows for selection of recombinant molecules when plated on  $E.\ coli$  lysogenic for  $P_2$ . Enzymes which generate the 5'-tetranucleotide end 5'GATC-3' (Bam HI, Bgl II, Bcl I), are compatible for cloning into this vector. Particularly useful is the ability to clone DNA fragments produced by random digestions with Sau 3A which has a 4 base recognition sequence of 5'IGATC-3'. BRL qualifies each lot of  $\lambda$  1059 DNA for its ability to be packaged into  $\lambda$  particles under  $in\ vitro$  packaging conditions.

Circle No. 52 on Reader Inquiry Card.

## Vaccinia Virus Capping Enzyme

Bethesda Research Laboratories is the sole commercial source of Vaccinia Capping Enzyme, which has three major applications in molecular biology. First, capping enzyme has been used to map transcription initiation sites of Xenopus laevis, preribosomal RNA, fibroin mRNA of Bombyx mori, early vaccinia virus transcripts and early herpes virus transcripts. Second, RNAs of satellite necrosis and influenza virus have been labeled by capping enzyme prior to sequence determination. Finally, capping enzyme has been used to study the role of the cap structure in mRNA binding to ribosomes and translation.

Circle No. 53 on Reader Inquiry Card.

## PRODUCT REVIEW

## Neisseria testing

A positive control kit, N. Microtech, for confirmatory testing of various Neisseria species has been announced by University Micro Reference Laboratory. The kit contains 20 gels each of Neisseria gonorrhoeae, N. meningitidis, N. sicca, Branhamella catarrhalis and N. lactamicus. A gel is either streaked onto a plate or inoculated into the appropriate medium and incubated in a 4% CO<sub>2</sub> atmosphere. Applications include evaluation of medium for ability to support growth and analysis of standard methods of identification of clinical specimens.

Circle No. 100 on Reader Enquiry Card.

## Antibiotic susceptibility

A MANUAL now available from Mast Laboratories describes their range of antibiotic susceptibility testing products. Included are antibiotic susceptibility disks, agar dilution products, inoculators and other accessory products.

Circle No. 101 on Reader Enquiry Card.

## Spiral plater

Two new spiral plater instruments have been designed by Don Whitley to supercede the existing B250 models. The new model C retains the alternate deposition volumes of the B250 whilst reducing the plating time from 23 to 15 s for a 10-cm plate. An optional extra is a uniform cam which gives even deposition of sample across the plate. Developed for laboratories where standardized routine plating requires high operator productivity, model D has a single deposition volume of  $50\,\mu 1$  for 10-cm plates and an automatic plating cycle which has reduced plating time to 7 s.

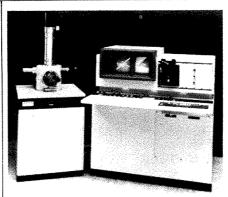

Circle No. 102 on Reader Enquiry Card.

## Viable counts

LUMAC instrumentation and reagents allow rapid microbial counting by the bioluminescence method. This is a rapid, accurate method for quantification of viable cells — a bacterial count is obtained in 30 s. It is useful where a quick result is desirable, for example, urine screening, contamination of food and dairy products, and water testing. It is also possible to count somatic cells, for example in tissue culture work.

Circle No. 103 on Reader Enquiry Card.

## **Automatic focus SEM**

A NEW, computer-controlled scanning electron microscope is available from Hitachi, Scientific Instruments. The S-520 provides resolutions of 60 Å, at magnifications from  $\times$  20 to  $\times$  200,000. Accelerating voltage range is 1-30 kV, selectable in 1 kV steps. A key feature of the S-520 is pushbutton-controlled automatic focus, which is achieved in 2 s, at magnifications up to  $\times$  50,000 and at working distances of 5-35 mm. An automated magnification system permits precise magnification settings in seconds and includes automatic brightness and contrast control, automatic 'quicklook' mode ( $\times 1,000$ ), a micron marker and one-button camera operation. All operating parameters are displayed automatically on the CRT, and a keyboard allows direct entry of other data. The standard S-520 stage has a 4-inch specimen chamber; a stage is available for semiconductor applications that handles 5-inch wafers and masks.

Circle No. 104 on Reader Enquiry Card.

## Instant photomicrography

An instant photomicrophy system, the SX-70, which produces high quality, detailed, full-colour microscopic images, has been introduced by Polaroid. The system has automatic exposure control and attaches easily to many microscopes. The SX-70 includes the new Polaroid SX-70 microscope adapter, a time-zero autofocus land camera model 2, and type 778 land film. The compact microscope adapter accepts folding single lens reflex SX-70 cameras and fits monocular and binocular microscopes or other optical instruments with eyepiece or phototubes of diameters between 24 and 40 mm. Adapter and camera electronics are linked to provide automatic exposure between 0.1 and 12.5 s. Circle No. 105 on Reader Enquiry Card.

PRODUCT REVIEW — The product review this week includes items for microbiology. The notes on these pages are prepared from information provided by the manufacturers. For more details use the reader enquiry card bound inside the journal. The next product review (26 November) deals with biochemicals.

## **Bacterial analysis**

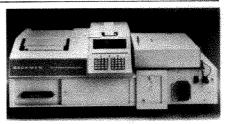

To detect bacterial contamination that may interfere with analyses, Millipore have produced the SPC sampler. This provides results equivalent to standard methods and the entire sampling procedure takes less than 2 min.

Circle No. 106 on Reader Enquiry Card.

## Media supplements

CULTURE media supplements in tablet form are now available from Mast Laboratories. Selectatabs are freeze-dried tablets containing one or more selective agents in an inert non-interfering carrier substance. On addition to the appropriate volume of medium, the Selectatab dissolves and a specific concentration(s) of the selective agent(s) is achieved. Selectatabs are available for the selective isolation of anaerobes, pathogenic Neisseria, pneumococci and Bordetella sp. Also available is a Selectatab for the prevention of swarming by Proteus sp.

Circle No. 107 on Reader Enquiry Card.

## Microplate analyser

As an accessory to the DU-8 spectrophotometer slab gel scanning system, Beckman Instruments has introduced the Microplate Analyzer to provide convenient, accusate analysis of microtitration plates. The Microplate Analyzer can be used in enzyme-linked immunoabsorbent assays and in the screening of monoclonal antibody production, quantitative determinations of antibodies and antigens, and bacterial growth studies. The system is useful in any kinetic, end point or microchemistry analyses.

Circle No. 108 on Reader Enquiry Card.

## Specimen handling

DANGERS associated with the taking and handling of swab specimens have been minimized by the development of Transwab, available from Medical Wire & Equipment. A new design of swab cap, used in all the units now supplied, has an elongated 'skirt' which completely encircles the top of the transtube, so making it almost impossible for the user's fingers to come into contact with any potentially infected part of either swab or tube. This eliminates the risk of cross-infection associated with the normal type of plug cap.

Circle No. 109 on Reader Enquiry Card.

## Anaerobic work station

An anaerobic work station which allows the operator to use bare hands whilst manipulating cultures at incubator temperatures has been developed by Don Whitley Scientific. Specimens can also be passed in and out of the cabinet through a special sleeve and glove port system without using the main microprocessorcontrolled interchange lock. The cabinet is fitted with automatic relative humidity control and external catalyst, atmospheric scrubber and dessicant canisters. The atmosphere is strictly controlled ensuring the earliest possible isolation of fastidious anaerobes. The cabinet accommodates 500 Petri dishes and allows ample space for inoculation, manipulation and examination of cultures.

Circle No.110 on Reader Enquiry Card.

## Agarose sampler kit

ON offer from Marine Colloids is a new agarose sampler kit. Included in the sampler are five of FMC Corporation's most popular agaroses covering almost all applications, including electrophoresis of proteins, nucleic acids and cells. One of these is SeaPlaque, a low-gelling temperature agarose used for preparative electrophoresis of nucleic acids and proteins, cell culture and cloning.

Circle No.111 on Reader Enquiry Card.

## Microfiltration

POLYCARBONATE and polyester capillary pore membranes are described in a new brochure from Nucleopore Corporation. These membranes alow high-resolution viewing against an unobtrusive two-dimensional background, advantageous in chemotaxis, exfoliate cytology, rheology, virology and other fields. Information on pore sizes, flow rates and applications are included in the brochure.

Circle No.112 on Reader Enquiry Card.

## **Fermenter**

A NEW fermentation vessel from Life Science Laboratories is available in 15 or 20l total volume, with the vessel, drive motor and all fluidic connections/fittings etc. mounted on a mobile trolley. The system is designed for in situ steam sterilization and can be operated at pressures of up to 2 bar g. The agitation system incorporates a double mechanical seal, which ensures sterility by maintaining positive pressure of sterile air in the seal housing. Air then enters the vessel by a rotating sparger. High oxygen transfer rates are possible with the 1.25 h.p. motor. A separate bench-standing cabinet contains compact instrumentation offering digital display of fermentation parameters, accurate control and computer-compatible output/control input circuitry.

Circle No.113 on Reader Enquiry Card.

## Dissolved oxygen meter

A portable dissolved oxygen/B.O.D. meter for use in wastewater, B.O.D. and other environmental monitoring applications has been developed by L.G. Nester. Featuring a range of 0-20 p.p.m. and a LCD readout, the model 8500 operates with either a submersible probe for wastewater pond and stream applications or a tapered B.O.D. probe for laboratory use. Both probes eliminate membrane changing, electrolyte replacement and the need for mechanical agitators or stirrers. Circle No.114 on Reader Enquiry Card.

## Streptococcal identification

It is now possible to identify the viridans streptococci and  $\beta$ -haemolytic organisms that either cross-react or give doubtful results with serological identification methods, by using a new design of API 20STREP, which includes 30 taxa on its data base. The tests are more easily interpreted and the centrifugation step required by the previous system has been eliminated. Circle No.115 on Reader Enquiry Card.

## Sampler loop

To avoid the hazards of splatter and aerosol spread, Hughes and Hughes Ltd. have produced a new sterile loop, made from polystyrene and sterilized by yirradiation. It performs the same function as a wire loop but incorporates the following features: calibration for semi-quantitative plating and counting, heel that allows easy spreading to give discrete colonies, an incorporated colony picker which avoids the need for a separate wire, and serrated section for easier disintegration of sputum or faeces.

Circle No. 116 on Reader Enquiry Card.

## Microbiology products

INCLUDED in the range of microbiology equipment from Griffin & George are autoclaves, sterilizers and associated equipment, culture bottles, Petri dishes, transfer chamber, incubators, refrigerators, colony counter and anaerobic jar. New to the range are Wipex disinfecting cloths which are impregnated with disinfectant and give complete disinfection on contact. Indicator stripes on the cloths show when the disinfectant is exhausted. They can be used for cleaning laboratory benches, transfer chambers, animal cages, washrooms, etc.

Circle No.117 on Reader Enquiry Card.

## **BIOLOGICAL SAFETY CABINET**

If you are ordering your biological safety cabinet from a multi-item catalog— You are probably paying too much!

## NUAIRE PRODUCTS PRODUCE COMPLETE SAFETY AND UTILITY . . .

Sircle No.23 on Reader Enquiry Card.

## Anaerobe identification

A SYSTEM for simple and rapid presumptive identification of the most frequently encountered clinical anaerobes, has been developed by Flow Laboratories. The system consists of a broth tube, Anaerobe-tek broth, a plate of Anaerobetek, two reagents, Flow gelatinase and Flow indole II, and a computer code book. Anaerobe-tek broth serves as a cell suspension medium for the inoculation of the Anaerobe-tek plate, which consists of eleven peripheral wells and a central well containing solid media for the determination of 15 different biochemical parameters. Anaerobe-tek allows the following evaluations: hydrogen sulphide and indole production; activity of lecithinase, lipase and catalase and bile tolerance, among others. These parameters, together with Gram reaction, spore formation and cell morphology, permit numerical identification codes to be generated for a total of 18 test criteria.

Circle No.118 on Reader Enquiry Card.

## Fluorescence microscopy

FLUOROCHROMATIC methods that require incident-light excitation are now commonly used in immunofluorescence microscopy, for example, in microbiology and phytopathology. Carl Zeiss Jena have produced for this purpose the Laboval 2a.fl incident-light fluorescence microscope, which has filter systems for excitation in the range 366-546 nm and apochromatic imaging optics of high aperture.

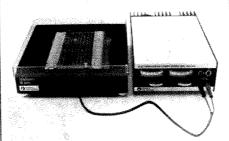

Circle No.119 on Reader Enquiry Card.

## Microdispenser

ADJUSTABLE for volumes from 0.01 to 0.1 ml, the Micro repetitive dispenser from Tri-Continent can fit most bottles and serum vials from 5 to 500 ml. Two models are offered: one made of polypropylene, stainless steel and glass, the other of Teflon, platinum and glass. Applications are in radioimmunossay, micotitre assays,

Circle No. 120 on Reader Enquiry Card.

## **Immunoelectrophoresis**

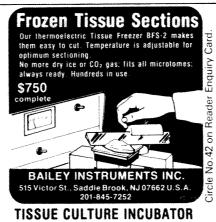

A NEW immunoelectrophoresis system for immunology and biomedical research has been introduced by Pharmacia Fine Chemicals. The system is designed for the fast running of all conventional forms of agarose gel electrophoresis and immunoelectrophoresis. All techniques are run on the flat-bed electrophoresis apparatus FBE-Immuno, which has an epoxy-resin construction resistant to coolant mixtures based on methanol, ethanol and ethylene glycol. The cooling plate itself has a large black surface area (152×250 mm) with a white printed pattern for easy visualization of immunoprecipitates, centering of the plates and direct sample application. An instruction manual is supplied with each FBE-Immuno apparatus.

Circle No.121 on Reader Enquiry Card.

## Poured plates

POURED plates can be obtained from Gibco Europe. Each finished plate is screened and packed immediately, in units of 10, into nylon bags which allow the release of the resultant condensation, reducing considerably random contamination. A recent addition to the poured plate range is Modified New York City Medium.

Circle No. 122 on Reader Enquiry Card.

Modular Incubator Chamber can be used for all types of tissue culture (aerobic, anaerobic). Easy to uset of tissue culture (aerobic, anaerobic). Easy to uset of tissue culture (aerobic, anaerobic). Easy to uset of appropriate temperature. Inexpensive, quantity discounts. billups-rothenberg, inc. pob 977 del mar, ca. 92014-0977 usa (714) 755-3309.

## Colony counter

AVAILABLE from Anderman & Company is a new pressure-sensitive counting system coupled to a digital counter. The Petri dish holder, which can accommodate dishes up to 90 mm in diameter, has been designed to allow 'edge counting' and colonies are evenly illuminated by diffused back lighting which eliminates operator fatigue. A new mechanical system ensures even pressure response over the entire surface of the Petri dish, and fast and accurate counting requires only slight pressure on the dish with any felt-tip pen or probe. An optional 114 mm diameter magnifier facilitates counting of densely populated cultures and fits conveniently on to the back of the colony counter body. A black background is supplied for 'side only' illumination, together with Wolffheugel grid plate and felt-tip pen.

Circle No. 123 on Reader Enquiry Card.

## Vortex mixer

PARTICULARLY useful for resuspending pellets after centrifugation, the new Monomixer, a vortex-type laboratory mixer from Sarstedt, Inc., has a variable speed control making it suitable for a variety of mixing applications. Thorough mixing in tubes and cuvettes up to 20 mm in diameter can be achieved easily with one hand by pressing the tube into the vortex cup.

## Bacterial assay system

THE new BACTEC system from Laboratory Impex provides a means of detecting the presence of both aerobic and anaerobic bacteria in a wide range of materials. Two models are available, the semi-automated model 301B, or the model 460, which is fully automatic and can examine up to 60 culture vials per h or up to 480 vials per day. Results are automatically displayed on a built-in digital printer. Circle No. 125 on Reader Enquiry Card.

## Sterile filtration

A pressure-driven, disposable device for sterilization of tissue culture media, media additives, buffers and other aqueous solutions is available from Millipore. The Sterivex-GS filter unit will sterilize up to 41 of media or 11 of medium with 10% serum Because the Sterivex unit is pressuredriven, protein denaturation problems common with vacuum-operated devices are eliminated. A hydrophobic filter automatically provides venting for air which might enter the fluid path. Both the air vent filter and 0.22-µm low-extractable membrane filter are supported to withstand high pressures.

Circle No. 126 on Reader Enquiry Card.

## Protective gloves

CRYOGLOVES, which repel steam heat, are available in mid-arm and shoulder length. They are equally protective against ultracold atmospheres (for example, walk-in freezers, dry ice). Cryogloves, from Harris LoTemp, are water repellent and do not contain asbestos.

## **AUTHORS WANTED** BY N.Y. PUBLISHER

A well-known New York subsidy book publisher is searching for manuscripts worthy of publication. Fiction, non-fiction, poetry, juveniles, travel, scientific, specialized and even controversial subjects will be considered. If you have a book length manuscript ready for publication (or are still working on it), and would like more information and a free booklet, please write:

Vantage Press, Dept. D-69 516 W. 34th St., New York, N.Y. 10001

## Temperature programmer

THE new Haake temperature programmer PG20, from Gallenkamp, can be used with Haake baths and circulators to give automatic time-linear temperature changes. All program parameters on the PG20 are set digitally, with rates variable from 0.01 to 9.99°C min-1.

Circle No. 128 on Reader Enquiry Card.

## $\beta$ -lactamase detection

AVAILABLE from Mast Laboratories, Intralactam is an acidimetric strip method for the rapid detection of  $\beta$ -lactamase. Originally designed to detect \(\beta\)-lactamase production in Haemophilus influenzae type B, it is suitable for use with gonococci and other Gram-negative bacteria. Results of such tests are available within 10 min. Detection of  $\beta$ -lactamase production in staphylococci is more difficult as the enzymes are produced only in small amounts, unless induced by the presence of a  $\beta$ -lactam antibiotic. Intralactam can detect staphylococcal \(\beta\)-lactamase by extending the reading time of the test. The use of a wet box prevents the strip from drying out and almost 100% of noninduced β-lactamase-producing staphylococci can be detected within 1-4 h. Circle No. 129 on Reader Enquiry Card.

## **Bacterial identification**

THE new system for identification of enteric and anaerobic organisms, Microbact from L.I.P., takes two forms, both using a microtitre plate. Microbact 12E consists of primary identification media for most isolates; Microbact 24E is a definitive identification set. The system is simple to set up and use and does not require a humidifying chamber. The user just has to peel back the tape covering the substrates, inoculate with a saline inoculum, replace the tape and incubate. After incubation the colour changes are noted with the aid of a chart. An 8-digit octal code system gives specific identification from the profile register.

Circle No. 130 on Reader Enquiry Card.

## Cryostar freezers

UNLIKE cascade freezers, the Queue Systems Cryostar freezers have only one compressor, and easily reach temperatures of ~75°C and ~100°C. The Cryostar line now includes a mechanically refrigerated -135°C cryogenic storage freezer, which can replace many expensive liquid nitrogen storage systems currently in use.

Circle No.131 on Reader Enquiry Card.

## Chromatography

PRODUCTION scale chromatography columns for microbial enzyme technology are available from Wright Scientific. A new range covers diameters from 70 to 1,000 mm, in glass, stainless steel and acrylic. All the columns provide good resolution due to the spreading and collection characteristics of the end cells. Anti-jetting devices have been added to the larger columns.

Circle No. 132 on Reader Enquiry Card.

## **Automatic spreading**

THE Denley Autospreader has been modified - the new fully electronically controlled version allows fast accurate platingout for primary culture. The series of spreading loops used is automatically sterilized between plates, or before use, to prevent cross-contamination. Fail-safe logic shuts down the instrument if the loops fail to sterilize electrically.

Circle No.133 on Reader Enquiry Card.

## **Incident light microscope**

An updated version of Reichert-Jung's MeF2 incident light microscope for routine photomicrography, the MeF2a, incorporates a fully automatic multi-camera system.

Circle No. 134 on Reader Enquiry Card.

## Cell disruptor

THE new model 350 Sonifier ultrasonic laboratory system from Branson Sonic Power Company is intended for ultrasonic disintegration and homogenization and is suitable for laboratory, pilot and production use. The power module of the 350 features a large front panel loading meter for ease of use. All units include a rear panel connection for the Sonifier temperature monitor TM-1 accessory that ensures accurate sonification exposure time while limiting the heat effects of the process. Typical applications for the Branson Sonifier include disruption of cells, bacteria, viruses and tissue.

Circle No.135 on Reader Enquiry Card.

## Safety cabinet

THE laminar air flow design of the Bio-Safe microbiological safety cabinet prevents cross-contamination of cultures being used side by side within the cabinet. There are two filters, one which supplies sterile air to the work area, the other which filters the air being exhausted from the cabinet; 70% of the air is recirculated while 30% is discharged at each pass. These filters are 99.99% effective for particles of  $\geq 0.3 \,\mu\text{m}$ . Circle No.136 on Reader Enquiry Card.

## Nature announces the first wall chart showing how the U.S. runs its science ...shows who makes U.S. science decisions, who gets the money, and how it's spent

If you're involved in making decisions about science, or if you're looking for your share of science funding, you need <a href="Nature">Nature</a>'s new 1981 guide to how the nation spends its science dollars and who controls that money.

Compiled by <u>Nature</u> from literally hundreds of sources, the wall chart offers data on actual dollars spent on science by government agencies, industry, foundations, universities, research and medical centers. The chart lists key U.S. government policy makers, with their addresses and phone numbers.

Most significantly, the chart shows the interlocking relationships within the science, engineering, and medical establishments.

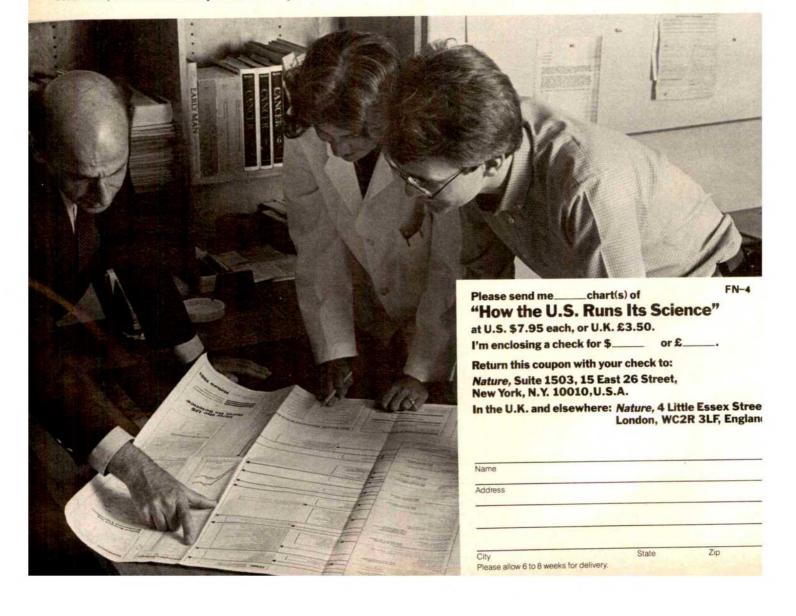

Designed as a fold-out that you can carry to meetings, or for hanging as a 2 x 3 ft. wall poster for permanent reference, the chart enables you to answer questions that

might otherwise take weeks of research to dig out. Compact, color-keyed, and handy, it will be an enormous aid to you and your colleagues. We strongly urge you to order sufficient copies to cover the needs of your entire staff or department.

## "How the U.S. Runs Its Science"

—another authoritative publication from <u>Nature</u>, for more than 100 years, the world's most respected source of science data.

12-month basis.

Send curriculum vitae, including a brief description of research experience and plans, and the names of three references by 15 December 1981 to: Genetics Search Committee, Department of Biological Sciences, Purdue University, West Lafayette, Ind 47907. Purdue University is an Affirmative Action Employer. (NW088)A

## CHIEF. ADULT HEALTH SECTION, CALIFORNIA DEPARTMENT OF HEALTH SERVICES, **SACRAMENTO**

Requires board certified (or board eligible)

## **PHYSICIAN**

Eligible to practice medicine in California, with demonstrated ability in public health and preventive medicine, to plan, organize and direct the work of the Adult Health Section. (Salary range \$4,524-\$5,320 per month.) This section administers programs in chronic disease control including cancer, hypertension and diabetes control. It is also responsible for health promotion through such programs as the Preventive Health Care for the Aging Program and the Health Education/Risk Reduction Program. Epidemiologic Research is conducted by the section's Human Population Laboratory. The Section includes a staff of 52 and an annual budget of approximately \$9 million in state and federal funds

Interested individuals should submit résumés no later than December 1981 to Kathleen Acree, MD, Chief, Preventive Medical Services Branch, California Department of Health Services, 714 P Street, Sacremento, California 95814 (Telephone 916-445-3151). An equal opportunity/affirmative action employer.

## A PROFESSORSHIP (C2)

will be available in the Department of Medical Microbiology at the Free University of Berlin. Preference will be given to a person with ample research experience in the field of T-cell dependent anti-infectious immunity. Obligations are, besides research, teaching and participation in the diagnostic bacteriological routine work, for the latter activity, no particular experience necessary.

For further information contact: Prof. Dr med. Helmut Hahn, Institute für Medizinische Mikrobiologie der Freien Universität Berlin Hindenburgdamm 27, D-1000 Berlin 45, West Germany. (W498)A

An der Formal- und Naturwissenschaftlichen Fakultät der Universität Wien ist die Planstelle eines Ordentlichen Universitätsprofessors für

## ANATOMIE UND PHYSIOLOGIE DER **PFLANZEN**

(mit Unterrichtsverpflichtung für Pharmazeuten)

zu besetzen.

Bewerbungen mit den üblichen Unterlagen (Lebenslauf und Schriftenverzeichnis) werden an das Dekanat der Formal- und Natur-wissenshaftlichen Fakultät der Universität Wien, A-1010 Wien, Dr Karl Lueger-Ring 1, bis 31. Jänner 1982 erbeten. (W500)A

## nature

has an immediate vacancy in London for an

## **ASSISTANT EDITOR**

to work primarily on the assessment of physical science manuscripts.

Essential qualifications:

- A good science degree
- Some knowledge of the earth sciences
- Some research experience
- A sense of literacy
- Wide general interests.

Applications, including a full curriculum vitae, should be plainly marked "Job application" and addressed to the Editor, Nature, Macmillan Journals, 4 Little Essex Street, London WC2R 3LF to arrive before 15 December 1981. Secondment for not less than two years would be appropriate.

(9927)A

## Higher Scientific Officer

The Rutherford Appleton Laboratory of the Science and Engineering Research Council require a Higher Scientific Officer to join a team engaged in the provision of the control centre, tracking station and science analysis facilities for the Infra-Red Astronomical Satellite (IRAS). This is a collaborative project involving the Netherlands, United States and the United Kingdom and the IRAS will be launched in the autumn of 1982.

The main responsibilities of the successful candidate will be as follows:

Maintaining a set of computer programs for 'Quick Look' Scientific Analysis data
from the satellite.

Providing documentation to instruct visiting Astronomers in using the science analysis programs and to provide support for visiting Astronomers in interpreting the IRAS data.

Applicants should have a degree or the equivalent in Physics, Mathematics, Astronomy or Computer Science together with at least 3 years post-graduate experience which should include a considerable amount of computer programming. Some experience of graphics and information retrieval techniques would be an advantage.

The salary is within the scales £6530 to £8589. Appointment to a salary scale point above the minimum may be considered for candidates with good qualifications and particularly relevant experience/specialist training.

We also offer excellent working conditions, local transport service, generous

holidays and a non-contributory superannuation scheme.

For further details and an application form, ring Lorna Bird in the Personnel Group on Abingdon (0235) 21900 quoting reference V N988 or write to her in the Personnel Group, Rutherford Appleton Laboratory, Chilton, Didcot, Oxon. OX110QX.

Closing date for applications: 3rd December 1981.

(9928)A

## Rutherford Appleton Laboratory

In the forefront

of research

## THE INSTITUTE FOR ADVANCED STUDY

will have several openings for members in theoretical physics and astrophysics for the academic year 1982-83. The positions are at a post-doctoral or higher level and applicants will be selected on the basis of their ability to do research in the areas of elementary particles, mathematical physics, astro-physics, plasma physics, general relativity and statistical mechanics. Preference is given to candidates who have received their PhD within the last year or two.

Postdoctoral members frequently collaborate with each other, with faculty members at the Institute or Princeton University, and with researchers at other institutions.

Appointments ae usually for no more than two years and support is typically full salary for postdoctorals and half salary for more senior persons. Women and minorities are encouraged to apply.

For more information write to Ms Valerie Nowak, Administrative Officer, School of Natural Science, The Institute for Advanced Study, Princeton, New Jersey 08540. Applications should be received by December 15, 1981. (NW1006)A

## **VACANCY NOTICE**

RESEARCH POSITION

## THE SWEDISH NATURAL SCIENCE RESEARCH COUNCIL

would welcome applications for a research position in the following field: Plasma- and Geocosmophysics related to EISCAT. Programme: Experimental and/or theoretical research associated with the measuring programme of EISCAT.

The position may be held at any research group within Sweden. The vacancy is intended to be filled on July 1, 1982, and runs for 3 years with a possibility to be prolonged for additional 3 years.

Salary: Salary-grade L18 plus allowances (at present Sw.Crs.9,575 per month).

Closing date: Applications should reach the Swedish Natural Science Research Council, Box 6711, S-113 85 Stockholm, Sweden, no later than December 17th 1981.

For particulars apply to Mrs Natalie Lunin, Tel: 08-151580. (W505)A

## PRINCETON UNIVERSITY

DEPARTMENT OF BIOLOGY

## CELL BIOLOGIST

The Biology Department invites applications for a faculty position in cell biology at the tenured or non-tenured level. Applicants working with a wide range of systems will be considered. Special attention will be given to applications in the area of development and differentiation, including cellular recognition, directed cell movements, and cell-cell interactions.

Our goal is to add an outstanding individual who will develop an active research program, attract graduate students and teach effectively. Interested candidates should send curriculum vitae, publication list, an outline of future research directions, and the names of three references to: Search Committee, c/o Malcolm Steinberg, Department of Biology, Princeton University, Princeton, New Jersey 08544, USA.

Princeton University is an Equal Opportunity/Affirmative Action Employer. (NW080)A

## THE ROWETT RESEARCH INSTITUTE

## SENIOR STATISTICIAN

(Head of Department)

(Senior Principal Scientific Officer)

A senior statistician is required as Head of the Institute's Biometry Department. Duties include general supervision of the department, which provides statistical, computing and other mathematical services for the Institute. The staff comprise four graduates and three data processors, plus two senior photographers who provide photographic and data presentation services. The department is in process of installing a new computer with conventional peripherals and a number of microcomputers on line, and for 18 months there will be an overlap with the old system.

The Head of Department should be able to provide innovative leadership and be experienced in the application of mathematics to nutrition and agriculture, and to participate personally in the statistical and mathematical activities of the Department.

Qualifications — A first or upper second class honours degree in a mathematical or natural science, with considerable relevant post-graduate experience.

Salary on the SPSO scale £14,329 to £17,418 per annum. Non-contributory superannuation scheme

Applications with curriculum vitae and the names of three referees should be submitted to the Secretary of the Institute, from whom further particulars are available. Closing date for applications within three weeks. (9885)A

## FACULTY POSITIONS IN PATHOLOGY

The Uniformed Services University School of Medicine invites applications for tenured or tenure track faculty appointments in the Department of Pathology at the levels of Professor, Associate Professor, or Associate Professor. Levels of appointment and salaries will be commensurate with training and experience. Candidates should have MD, PhD or related professional degrees, appropriate postdoctoral training or experience, teaching abilities, and demonstrated excellence in research.

Interested candidates should submit curriculum vitae, bibliography, and names of three professional referees by 30 November 1981 to Dr Robert Friedman, Chairman, Department of Pathology, c/o Personnel/Manpower Division, Uniformed Services University of the Health Sciences, 4301 Jones Bridge Road, Bethesda, MD 20014. The Uniformed Services University is an equal opportunity/affirmative action employer. (NW061)A

# For the innovative, there's no place quite like Syva.

## Discover creative freedom with the innovators in medical diagnostics.

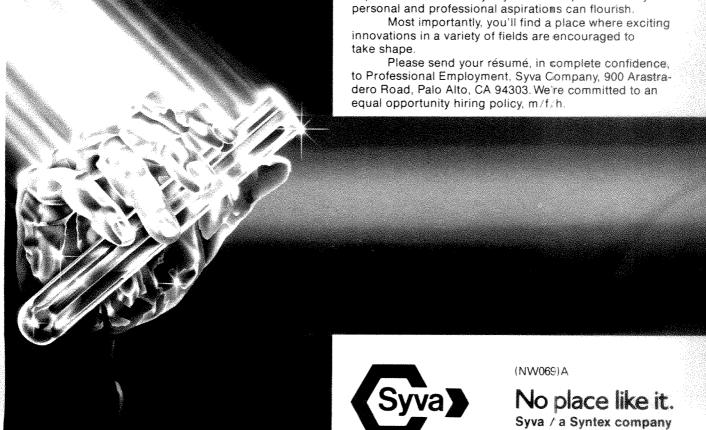

We believe that talent, creativity and determination aren't worth much without a good place to use them. So over the years, Syva has been committed to providing our people with an environment conducive to creative freedom and independent thinking. And that philosophy has been an overwhelming success in turning medical diagnostic concepts into practical, life-giving contributions.

Syva's proprietary products are used for the measurement of therapeutic drugs, endogenous sub-

stances and abused drugs in the body, with continued research and development efforts promising many more applications. And the formation of our new Instrument Division will ensure that Syva flourishes as a full-service organization, providing instruments, as well as reagents, service, and education to our customers.

Just as our accomplishments in the past are the result of innovative contributions from highly skilled professionals, Syva's continued growth and success depend on more of the same—more innovations from talented microbiologists, biochemists, organic chemists, technical service representatives and sales representatives. And since we're depending on whole-hearted determination to continue our success, our people depend on us for one of the most attractive work environments in the industry.

From a style of participatory management that encourages free and open discussion to the most advanced facilities in the business; from the beautiful San Francisco Bay Area's wealth of cultural and recreational resources to competitive salaries and benefits, when you explore a career with Syva you'll find a place where your personal and professional aspirations can flourish

The Swiss Federal Institute of Technology in Zurich invites applications for a

## Professorship in **Microbiology**

The duties of the professor include teaching in microbial metabolism and soil microbiology in the Faculties of Agriculture and Natural Science. Teaching courses should examine the connections between microbial physiology and ecological behaviour.

Detailed knowledge of microbial physiology and a broad understanding of the activities of micro-organisms in biogeochemical cycles are required. These should be the basis for research into nutrient cycling in agricultural and natural soils.

Applicants should have experience in university teaching and in directing research teams. Close collaboration with existing research teams in the field of microbiology is desired.

Applications with curriculum vitae and a list of publications should be submitted by December 31, 1981, to Professor H. Ursprung, President, Swiss Federal Institute of Technology, ETH-Zentrum, CH-8092 Zurich.

(W499)A

## COWLES DISTINGUISHED **PROFESSORSHIP** IN BIOLOGY

Trinity University invites applications and seeks nominations for an outstanding scientist to fill the position of the Ruth C. and Andrew G. Cowles Distinguished Professorship in Biology. The Professorship is to augment a well established curriculum in biological sciences and to contribute significantly to the academic community.

The University seeks an individual of distinguished reputation in the biological sciences with an established record of excellence in teaching and scholarship, as well as a commitment to liberal arts education. The Cowles Professor will be selected from candidates with superior credentials in the biological sciences. Developmental biology and/or genetics are fields of particular interest.

Trinity University is an independent institution committed to excellence in the liberal arts and selected professional programs, including engineering. Present enrollment is 3,200, of which 2,600 are undergraduates. The Department of Biology has nine faculty members with the earned doctorate degree and 150 majors. The department offers a Bachelor of Arts, Bachelor of Science, and Master of Science degrees. Trinity University is located in the San Antonio metropolitan area which has a population of over one million.

Nominations and applications must be received by December 31, 1981, and should be mailed to:

Dr. Harold D. Murray, Chairman Department of Biology **Trinity University** San Antonio, Texas 78284

(NW082)A

An equal opportunity affirmative action employer

**CAMBRIDGE, MASSACHUSETTS** 

Positions are available for scientists at all levels who are skilled in the areas of:

Microbial Physiology Genetics **Cell Biology Nucleic Acid Biochemistry Recombinant DNA Technology** 

**Biochemistry Organic Chemistry** Enzymology **Protein Chemistry** 

Biogen is a biotechnology company with laboratories in the United States and Switzerland, developing commercial applications of molecular biology in the areas of agriculture, chemicals, pharmaceuticals and energy. We offer a challenging scientific career with the opportunity to interact with talented colleagues in a stimulating environment.

Research is currently underway in our laboratories in Cambridge and we are continuing to expand our staff and facilities during 1981-1982. seeking people in a variety of areas as we initiate new projects.

Biogen offers a competitive salary and benefits package

Reply to: Personnel Director, Biogen Inc., 50 Church Street, Cambridge, MA 02138. Please send your résumé and a list of three individuals whom we may contact for references on your behalf. All is an equal (NW071)A replies will be evaluated in confidence. Biogen opportunity employer.

NEUROPHYSIOLOGY / Respiratory Physiology: Research Associate Position, available immediately, for studies of neural and chemical control of ventilation. Doctorate required and postdoctoral experience preferred. Salary commensurate with experience. Curriculum vitae and names of three referees should be sent to: Walter M St John, PhD, Depart-ment of Physiology, Dartmouth Medical School, Hanover, NH 03755, USA. (Dartmouth College is an equal opportunity, affirmative action (male/female) employer.)
(NW055)A

> **UNIVERSITY OF MELBOURNE**

DEPARTMENT OF SURGERY Austin Hospital and

Repatriation General Hospital RESEARCH FELLOW GRADE 1

(Limited Tenure)

A Research Fellow is required to join a team based at the Austin Hospital studying the ontogeny, function and metabolism of peptides of the gut and the brain. The work involves research on foetal and adult sheep and in man.

Applicants should have a PhD (or near completion), background training in biochemistry, and experience in one of the following: physiology, pharmacology, or zoology. Previous studies in some of these areas would be an advantage; peptide chemistry including HPLC, peptide receptors, isolated organ perfusion.

Salary within the range of \$A17,083 — \$A19,570 per annum.

Enquiries to Dr A Shulkes or Professor K Hardy, Department of Surgery, Austin Hospital, Melbourne,

Further information, including details of application procedure and conditions of appointment, is available from the Staff Officer, University of Melbourne, Parkville, Victoria 3052, Australia. Applications referring to position number 546 A08 should be addressed to the Staff Officer, and close on 18 December 1981. (9912)A December 1981.

ASSISTANT/Associate Professor. Must have research interest in cellular and molecular aspects of hostparasite interaction. Postdoctoral experience in microbial physiology, molecular genetics, immunology, virology, or pathogenic organisms required. Teaching commitment in medical microbiology and graduate courses required. Closing date 15 February 1982. Send curriculum vitae, description of professional aspirations, and names of three referees to Dr Byron Burlingham, Department of Microbiology, School of Medicine, East Carolina University, Greenville, NC 27834. An Equal Opportunity through Affirmative Action Employer. (NW077)A

## CITY OF LONDON **POLYTECHNIC**

DEPARTMENT OF BIOLOGICAL SCIENCES Applications are invited for a

## RESEARCH ASSISTANT

to study the cell wall/outer membrane structure of Desulfovibrio with particular emphasis on the adhesion of the cells to metal surfaces. Applicants should have a good honours degree, preferably in Cell/Biochemistry, Chemistry or Microbiology. Experience of chromatographic and other analytical techniques will be an advantage. The post is available immediately and is tenable for two years and may be extended for a third year. The successful applicant will be expected to register for a higher degree with the

Salary (Researcher A) £4,386 pa in the first year of appointment, rising to £4,602 in the second year £4,818 in the third year. London Allowance of £759 pa is also paid.

Please apply in writing giving full curriculum vitae and the names and addresses of two referees to Mrs C. Gaylarde, Department of Biological Sciences, Old Castle Street, London, El 7NT. The closing date will be ten days from the appearance of this advertisement. (9893)A advertisement.

MEDICAL RESEARCH COUNCIL
CLINICAL AND POPULATION CYTOGENETICS UNIT

Cytogeneticist

Applications are invited for a short-term non-clinical scientist post (Grade II) in this MRC Unit, tenable for three years. Candidates of immediately post-doctoral or equivalent status will be preferred.

The appointee will work with a small group studying the chromosome changes that occur in patients with haematological disorders. Some experience in human cytogenetics would be an advantage but is not essential.

Remuneration will be at an appropriate point on the scales for University non-clinical academic staff.

Further information may be obtained from Mr. Alasdair Douglas, MRC Clinical and Population Cytogenetics Unit, Western General Hospital, Crewe Road, Edinburgh EH4 2XU, Tel. No. 031-332 2471, with whom applications — including a full CV and the names and addresses of two professional referees should be lodged by 5th December, 1981.

## **RESEARCH POSITION**

(C1, Hochschulassistent) in antiinfective immunology available Applicants (PhD or MD) should have een interest and experience in antiinfective immunology (T cell cloning, receptor analysis, biochemistry of

This position allows ample time for research; in addition, participation in teaching lectures and courses in medical microbiology as well as work in the routine laboratory are obligatory. In the latter field, no special experience is required.

For further information contact: Prof. Dr med. Helmut Hahn, Institute für Medizinische Mikrobiologie der Freien Universität Berlin Hindenburgdamm 27, D-1000 Berlin 45, West Germany. (W497)A

## MANCHESTER AREA **HEALTH AUTHORITY** (TEACHING) CENTRAL DISTRICT **Tissue Typing Laboratory** Saint Mary's Hospital POST DOCTORAL WORKER

To join the North West Regional Immunogenetics Laboratory to undertake Research and Develop-ment work in the field of Renal Transplantation. The primary aim of the project is to improve transplant success by serological and cellular methods. Local facilities would allow access to many established and new

Interested persons with experience in Immunology, Genetic Markers, Tissue Typing or Cell Culture Techniques may discuss this vacancy with Dr Phillip Dyer (Tel 061-224 9633 ext 471).

Appointment will be according to qualifications at Senior Scientific
Officer or Scientific Officer level on
the Whitley Council PTA Scale. This
post is supported by the Manchester and North West Regional Kidney Research Association and is annually renewable.

Applications to Professor R Harris, Department of Medical Genetics, Saint Mary's Hospital, Hathersage Road, Manchester M13 (9919)A

An der Formal- und Naturwissenschaftlichen Fakultät der Universität Wien ist die Planstelle eines Ordentlichen Universitätsprofessors für

## SYSTEMATISCHE BOTANIK (mit Unterrichtsverpflichtung für Pharmazeuten)

zu besetzen.

Bewerbungen mit den üblichen Unterlagen (Lebenslauf und Schrif-Dekanat der Formal- und Schriftenverzeichnis) werden an das Dekanat der Formal- und Naturwissenshaftlichen Fakultät der Universität Wien, A-1010 Wien, Dr Karl Lueger-Ring 1, bis 31. Jänner 1982 erbeten (WS01) (W501)A 1982 erbeten.

## ASSISTANT OR ASSOCIATE **PROFESSOR AND** ASSISTANT OR ASSOCIATE **AGRONOMIST**

The Department of Agronomy and Range Science invites applications for an Assistant or Associate Professor/Assistant or Associate Agronomist position at the University of California/Agricultural Experiment Station, Davis, CA. Research should focus on integrative crop physiology and ecology as they relate to factors limiting performance of crop plant communities. The can-didate will be expected to develop an active research program pertaining to agronomic crops in California. Teaching duties will include one or two courses in either the undergraduate Agronomy or Plant Science programs and/or the Agronomy graduate program. A PhD in a suitable field is required. The level of appointment will be commensurate the candidates experience.

Send a statement of research interests, curriculum vitae, transcripts, list of publications, and names of three references by February 26, 1982 to: R L Travis, Search Committee Chair, Department of Agronomy and Range Science, University of California, Davis, CA

The University of California is an Equal Opportunity/Affirmative Action Employer. (NW079)A Action Employer.

## CSIRO AUSTRALIA Research Scientist/ Senior Research **Scientist**

\$A19,662 - \$A28,564

Division of Irrigation Research Griffith, New South Wales

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7500 employees - 2700 of whom are research and professional scientists located in Divisions and Sections throughout Australia.

Field: Root Zone Agronomy

General: Research of the Division is concerned with general problems of water management and with the efficient use of water and soils in irrigation agriculture and ecological consequences of inefficiencies. Fine textured soils of low permeability predominate in the irrigation areas of Australia and root zone limitations are often a major factor causing low yields in intensive systems of row crop production. A major goal of this Division is to develop management techniques for minimizing these limitations.

Duties: To undertake research on root zone factors causing low crop yields on irrigated fine textured soils. A major emphasis will be on the interrelationships of water and oxygen movement under systems of flood and controlled irrigation. The appointee will be required to oversee the development of a drainage lysimeter facility to study the impact of different techniques of surface irrigation, drainage and water table management on crop growth on the major irrigated soils of south east Australia. This work will provide the theoretical basis for a field program examining potential solutions to the low yield problem.

Qualifications: A PhD degree or equivalent in Agronomy or Soil Science and a proven capacity for independent original work at the postdoctoral level. Research experience with irrigation agronomy and soil drianage lysimeters would be an advantage.

enure: Indefinite with Superannuation

Applications: In writing stating full professional details, the names of at least two professional referees, quoting reference number A3017 should reach: The Acting Chief, Division of Irrigation Research, CSIRO, Private Mail Bag, GRIFFITH NSW 2680, AUSTRALIA, by 18 December 1981.

(9917)A

## AGRICULTURAL RESEARCH COUNCIL FOOD RESEARCH INSTITUTE

## **NUTRITION & FOOD QUALITY DIVISION NUTRITIONIST** (Scientific Officer)

The Food Research Institute has a vacancy for a Nutritionist in the Nutrition & Food Quality Division. This post is in the new group concerned with studies of the methodology of measuring food intake in man. The officer will be responsible for setting up and operating a nutrient information and data base. The post calls for a sound background in nutrition and an interest in the application of computers. The Institute shares computer facilities with the John Innes Institute and there is an active computer group with which this officer will interact.

Qualifications: A first or upper second class Honours degree in Nutrition or Food Science with experience of, and interest in, the application of computer techniques.

Salary: On a scale £5,176 - £6,964. Non-contributory superannuation

Further particulars and application form from the Secretary, Food Research Institute, Colney Lane, Norwich NR4 7UA quoting ref. 81/42. Closing date: 3rd December 1981. (9898)A

## ANGLO-AUSTRALIAN OBSERVATORY

## RESEARCH **ASTRONOMERS**

The Anglo-Australian Observatory comprises the 3.9 metre telescope near Coonabarabran N.S.W. and a laboratory at Epping near Sydney, Australia. There is a scientific staff of 6 astronomers nominated by the United Kingdom and Australia One position for each country becomes vacant between March and October 1982.

Candidates should have a strong background in physics or astrophysics. Appointments will be fixed terms of 1 to 5 years, with salaries in the range \$19,662 to \$38,921 per year, plus other allowances, fares etc. The successful applicants will have the choice of being based at the laboratory or the telescope. They will provide assistance to visiting astronomers, and contribute to the development, maintenance and general running of the AAT and its instrumentation. They will have opportunities for personal research and collaboration with Australian and UK astronomers.

Applications should include:

- Age, citizenship, country of residence and marital status.
- Qualifications and experience, including date of PhD.
- Astronomical research projects for which telescope time will be sought. Sufficient information is required to show that the proposals would be competitive in applications to a time assignment committee.
- Any instrument development project in which the applicant is particularly interested.
- When applicant would be available to take up appointment.
- Length of appointment envisaged.
- Names and addresses of three referees.

Applicants should arrange for the three references to be sent directly to the Director by the closing date.

Enquiries and applications should be addressed to the Director, Anglo-Australian Observatory, PO Box 296, Epping N.S.W. 2121 Australia, and applications copied to Mr I. L. Midson, Science and Engineering Research Council, PO Box 18, North Star Avenue, Swindon SN2 1ET, Wiltshire, England.

The closing date for applications is 4 January 1982. (9926)A

## PLANT TISSUE CULTURE

PHYTOGEN, a leading genetic engineering company applying molecular biology and plant tissue culture techniques for the improvement of agriculturally important crops, has an immediate opening at the level of SENIOR SCIENTIST in the area of PLANT TISSUE CULTURE. Duties will include the supervision of projects involving protoplast culture and regeneration. The successful candidate will have demonstrated the ability to conduct creative, independent research, minimum of two years postdoctoral experience is required.

PHYTOGEN is located in Southern California and offers a stimulating working environment. Applications accompanied by a curriculum vitae and a list of publications should be sent to: PHYTOGEN, 101 Waverly Drive,

Pasadena, California 91105.

(NW087)A

## Institute of Geological Sciences **GEOPHYSICIST**

The Institute has a vacancy for a geophysicist at Higher Scientific Officer/Senior Scientific Officer level in its Hydrogeology Unit based at Wallingford, Oxon. The successful candidate will be required to assist with overseas geothermal projects. Duties will include project identification, the preparation and management of prefeasibility projects and also research into the latest geothermal exploration techniques. Collaboration with consulting engineers in the design and preparation of bids for commercial projects will also be required.

Age and Qualifications: Applicants should normally be under 32 and have a 1st or 2nd class honours degree in an appropriate subject.

Salary: Higher Scientific Officer £6,530 - £8,589. Senior Scientific Officer £8,209 - £10,322

Grade of appointment and starting pay will depend on qualifications and relevant experience.

Starting salary may be above the minimum. Occupational pension scheme. The Staff of the Council are not Civil Servants but their pay and conditions of service are similar to those of scientists in the Civil

For an application form to be returned by 7 December 1981 please contact: Establishments (Recruitment) Section, Institute of Geological Sciences, Exhibition Road, London SW7 2DE. Please quote reference SO/HY/81/1.

NATURAL ENVIRONMENT RESEARCH COUNCIL

(9897)A

## MEDICAL RESEARCH COUNCIL MAMMALIAN **DEVELOPMENT UNIT**

Applications are invited for a

## SHORT-TERM NON-CLINICAL SCIENTIFIC POST

in this MRC unit, tenable for 3 to 5 years, to study early mammalian development. Candidates of immediately post-doctoral or equivalent status will be preferred; molecular or bio-chemical experience will be particularly welcome.

Remuneration will be at an appropriate point on the scales for university non-clinical academic staff. Further information and an application form may be obtained from The Secretary, MRC Mammalian Development Unit, Wolfson House, 4 Stephenson Way, London NW1 2HE, with whom applications, including a full CV and the names of two professional referees should be lodged by December 31 1981. (9920)A

## LOUGHBOROUGH UNIVERSITY OF **TECHNOLOGY** Polymer Physics Applications are invited for a three-year post as POST-DOCTORAL RESEARCH ASSISTANT

to take a leading part in an inviestigation of mechanical changes in PVC during polymerization. The award is a co-operative one between SERC and ICI Petrochemicals Plastics Division. A flair for physical measurements and instrumentation is required. Research experience in relevant fields is important. Starting salary £6,880. Reply to Dr Ray Wetton, Department of Chemistry. Loughborough, Leicestershire.

(9916)A

## **NEW YORK** MEDICAL COLLEGE **DEPARTMENT OF PHYSIOLOGY**

## POSTDOCTORAL RESEARCH **POSITION**

Available immediately under the sponsorship of Drs. Gabor Kaley and Edward J. Messina, Investigation of role of prostaglandins in regulation of microcriculation, hypertension and vascular reactivity. Background in microcirculation techniques, vascular smooth muscle work and small animal surgery preferred. Appointment is for one year. renewable for an additional year. Candidates should send CV, summary of research experience and names of three references to: Gabor Kaley, PhD, Professor and Chairman, Department of Physiology, New York Medical College, Valhalla, N.Y. 10595.

(NW072)A

## **GUY'S HOSPITAL** MEDICAL SCHOOL

## **POSTDOCTORAL** RESEARCH ASSISTANT

required as soon as possible until 30th November 1983 to join team investigating purine and pyrimidine metabolism in crippling inherited disorders. Preference given to Biochemistry graduate with some knowledge of the field and with experience in HPLC.

Salary for recently qualified PhD £6,070 plus £967 London Allowance.

Apply in writing, with full curriculum vitae, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, quoting (9900)A Ref PM

## UNIVERSITY OF CAPE TOWN LECTURER IN BOTANY

Applications are invited for the above post. Preference will be given to candidates with research experience in either Ecophysiology or Marine Ecology/Phychology.

Appointment, depending on qualifications and experience will be made on the salary scale R10,995  $\times$  675 - R14,370  $\times$  810 - R19,230 per annum. In addition, a service bonus of nearly one month's salary is payable annually.

Staff benefits include 75% rebate on tuition fees for dependants at UCT, generous study leave privileges, housing subsidy subject to certain conditions, pension fund, medical aid and group life assurance schemes.

Applicants should submit a curriculum vitae, stating qualifications, teaching and research experience, publications, present salary, the date duty could be assumed and the names and addresses of three referees.

Further information may be obtained from the Registrar, (attention: Appointments Office), University of Cape Town, Rondebosch, 7700, by whom applications (quoting ref. no. . . .) must br received not later than 15th January 1982

not later than 15th January 1982.

The University's policy is not to discriminate in the appointment of staff on the grounds of sex, race or religion. Further information on the implementation of this policy is obtainable from the Registrar. (W506)A

## CORNWALL AND ISLES OF SCILLY AREA HEALTH AUTHORITY

Royal Cornwall Hospital (Treliske) Truro

## PRINCIPAL PHYSICIST

A new Department of Medical Physics, based at the Royal Cornwall Hospital (Treliske) Truro, is to be established in order to provide and expand the Medical Physics Services currently provided from Plymouth.

The Department will be developed in two phases, the main functions in Phase I being: (a) Radiation Protection; (b) Radiotherapy Physics; (c) Scientific Support Services in Nuclear Medicine; (d) Clinical Equipment Management in Electronics.

Premises available in Phase I consist of two laboratory/work-shops. Supporting staff will initially be two technicians MPT III) and a half-time secretary.

Plans for Phase II are not finalised but are in the Area Strategic plan. The functions will depend on clinical demand and on the effectiveness and enthusiasm of the Principal Physicist and his staff.

A physicist is now sought with the appropriate qualifications, and with substantial experience and proven success in most of the fields detailed above to set up the new Department.

The person appointed will initially be responsible to the Chief Physicist in Plymouth, but from the outset will have responsibility for internal management.

The facilities of the department at Plymouth will continue to be available as required.

Job description and application forms obtainable from the Personnel Officer, Cornwall and Isles of Scilly AHA, St. Clement Vean, Truro, Cornwall.

Full details are obtainable from Mr R.C.T. Buchan, Chief Physicist, Freedom Fields Hospital, Plymouth (752) 834267). Closing date: 4 weeks from the appearance of this notice.

(9894)A

## INSTITUTE OF ANIMAL PHYSIOLOGY

Babraham, Cambridge CB2 4AT

## RESEARCH SCIENTIST

required in the Physiology Department to undertake research into one of the following fields: hormonal control of gene expression; cell surface and membrane properties particularly of embryonic tissues; or the mode of action of gut peptides. Applications are invited from candidates interested in the endocrine control of reproduction, lactation or digestion. 1st or 2 (i) honours degree and at least two years' relevant postgraduate experience for HSO and four for SSO. A PhD would be preferred. Salary in Higher Scientific Officer Scale (£6,530 — £8,589) or Senior Scientific Officer Scale (£8,209 — £10,322) p.a. Noncontributory superannuation scheme.

Application forms and further details from the Secretary of the Institute, quoting reference PD7. Closing date 3 December 1981.

(9914)A

## **SCIENTIST**

There is a vacancy in the Medical Research Council Pneumoconiosis Unit for an X-ray Crystallographer to carry out research on the structure of mineral and man-made fibres of respirable size. The appointee will ioin the Physics Section which is engaged in development of methods to predict the potential health hazards of new fibrous materials and in investigation of the requirements for fibre carcinogenicity. The appointment will be for three years in the first instance and will be subject to MRC conditions for non-clinical scientific staff. The salary range is £5,505 — £8,845 (subject to review). Qualifications for entry are broadly similar to those for University

Applications should be sent to the Administrative Officer, MRC Pneumoconiosis Unit, Llandough Hospital, Penarth, S. Glam., CF6 1XW. (9909)A

## ©SIRO AUSTRALIA Ceramics Scientist

\$A19.662 - \$A28,564

Division of Materials Science Advanced Materials Laboratory Fishermen's Bend, Victoria

CSIRO has a broad charter for research into primary and secondary industry areas. The Organization has approximately 7500 employees — 2700 of whom are research and professional scientists — located in Divisions and Sections throughout Australia.

Field: Electron Microscopy.

General: The Division has two laboratories, one located at the University of Melbourne (Catalysis and Surface Science) and the other at Fishermen's Bend. The appointee will be located at the Fishermen's Bend Laboratory where the main interests are in the mechanical properties of advanced ceramics and the electrical properties of ceramic electrolytes. There is wide interest in the Division's zirconia toughened ceramics.

**Duties:** The appointee will collaborate with a group studying the mechanical and thermomechanical properties of multiphase ceramics, including oxides, nitrides and carbides. Initially the appointee will work on sintering problems in the field of zirconia toughened ceramics.

Qualifications: A PhD degree or equivalent in an appropriate field, with demonstrated research ability and a thorough knowledge of Transmission Electron Microscopy, Scanning Electron Microscopy and Electron Analytical Techniques. A knowledge of sintering processes in ceramics and experience with ceramic powder characterisation would be desirable.

Tenure: 3 years. Superannuation benefits available.

Applications: In writing stating full personal and professional details, the names of at least two referees and quoting reference number A2728 should reach: The Officer-in-Charge, Advanced Materials Laboratory, Division of Materials Science, CSIRO, PO Box 4331, MELBOURNE VIC 3001 AUSTRALIA, by 18 December 1981.

## CELLTECH

## SEROLOGIST/HAEMATOLOGIST

Celltech is a new British Company, backed by the Government and City financial institutions, dedicated to the exploitation of discoveries in the field of biotechnology.

We are looking for a serologist or haematologist with about 3 years postodoctoral research experience in blood typing serology or related areas of immunohaematology to participate in a research programme designed to obtain, evaluate and develop new serological products. These products are most likely to be monoclonal antibodies and the successful candidate will be supported by our existing research effort in this field.

Salary will be in the range of £8,000 - £13,000, depending on age and experience.

Please send CV to the Personnel Department, Celltech Limited, 250 Bath Road, Slough, Berkshire St.1 4DY. Quoting ref. 120. (9915)A

## cetus

A pioneer in bioindustry since 1971, is currently seeking innovative professionals in the following areas:

## BIOCHIMISTE/PHARMACOLOGUE — REGION PARISIENNE

Un des principaux groupes pharmaceutiques français du secteur privé recherche un biochimiste expérimenté orienté vers la pharmacologie moléculaire pour un poste de haut niveau, ayant une expérience d'au moins cinq ans dans l'industrie pharmaceutique, ou ayant dirigé une importante Unité de recherches à l'Université, de préférence dans le domaine cardiovasculaire, SNC ou sécrétion gastrique.

Ce poste conviendrait à un candidat pouvant prouver son expérience par une liste importante de publications.

Envoyer CV et liste des publications sous référence W502, c/o Nature, Macmillans Journals, 4 Little Essex Street, London WC2R 3LF.

Discrétion assurée.

(W502)

## THE UNIVERSITY OF SHEFFIELD

Applications are invited from men and women for the following post:

## Research Assistant Department of Psychology

To work on an SERC funded project investigating the functions of the superior colliculus in rats, especially in relation to the ascending dopamine systems. Training in relevant neurobiological techniques provided. Informal enquiries to Dr. Peter Redgrave (0742 78555 ext 6556). Tenable for 16 months in the first instance. Initial salary up to £5,675 a year on Range IB. Applicants should supply the names of two referees. Quote ref: R646/2/G.

Closing date for all the above post is 10 December 1981. Particulars from (candidates must quote ref. no.) and applications to the Registrar and Secretary (Staffing), the Registrar and Secretary (Staffing), the University, Sheffield S102TN. (9921)A

## FORESTRY COMMISSION Decay in Amenity Trees

## Higher Scientific Officer/ Senior Scientific Officer

required in the Pathology Branch of the Forestry Commission, Forest Research Station, Alice Holt Lodge, Wrecclesham, Farnham, Surrey to undertake research into decay problems associated with amenity trees. The research programme will consist of a continuation of current research on the treatment of pruning wounds

This appointment will be made under a contract between the Forestry Commission and the Department of the Environment which terminates on 31 December 1983.

Qualifications: 1st or 2nd class degree in biological sciences. Research experience on decay fungi in trees would be a considerable advantage.

<code>Salary:</code> Within the range for HSO or SSO - depending on qualifications and experience, ie £6,530 - £10,322.

Note: This is a Contract appointment up to 31 December 1983.

Applications forms and further details are obtainable from Mrs K. Burt, Forestry Commission, Personnel Branch, 231 Corstorphine Road, Edinburgh EH127AT. Tel: 031-334 0303 ext 406. Completed applications should be returned not later than 10th December 1981.

GUY'S HOSPITAL Medical School, Occupational Health Research Unit, Department of Community Medicine. Graduate or Postdoctoral Research Assistant required for two years to develop a portable electronic device for measuring back stress. Applicants should have a degree in Electronic Physics, preferably with bioengineering training or comparable experience; interest in physiological and occupational aspects of low back pain desirable. Salary in range £5,285 to £7,700 or £6,070 to £10,575 according to qualifications and experience, plus £967 London Allowance. Apply in writing, with full curriculum vitae, to the Secretary, Guy's Hospital Medical School, London Bridge, SE1 9RT, from whom further information may be obtained. Please quote Ref C M. Telephone enquiries to Department of Community Medicine (01-407 7600 ext 2157).

## PROFESSIONAL RESEARCH ASSISTANT IN CARBOHYDRATE CHEMISTRY

To participate in the purification and structural analysis of biologically interesting complex carbohydrates using modern instrumentation such as NMR, GC, GC-MS, LC and LC-MS. Applicants should have the equivalent of a BSc or MSc in Chemistry or Biochemistry. Starting salary (between \$12,000 and \$16,000) will depend on experience. The University of Colorado is an affirmative action/equal opportunity employer.

Applications should be sent to

Applications should be sent to Michael McNeil or Peter Albersheim, Department of Chemistry, University of Colorado, Campus Box 215, Boulder, Colorado 80309, and should be received by December 31, 1981. (NW089)A

## UNIVERSITY OF SUSSEX

Medical Research Council Cell Mutation Unit

## BIOCHEMIST/ MOLECULAR BIOLOGIST

Applications are invited for a Short-Term Non-Clinical post in this MRC Unit tenable for 3 to 5 years according to age and experience of the successful candidate. Candidates of immediately post-doctoral or equivalent status will be preferred, but well qualified candidates with less than 3 years postgraduate experience will also be considered.

The successful candidate will work in a team studying the mechanisms of DNA repair in human cells. Some enzymological experience is desirable and the work will involve the application of recombinant DNA technology to human DNA repair genes.

Remuneration will be at an appropriate point on the scales for university non-clinical academic staff. Further information and an application form may be obtained from Dr A R Lehmann (tel: 0273 606755, ext 236). Application forms plus a full cv and the names of two professional referees should be sent to Mrs M Bunn, MRC Cell Mutation Unit, University of Sussex, Falmer, Brighton BN1 9QG by January 31st 1982. ## **MOLECULAR BIOLOGY**

The Microbiology Department at Case Western Reserve University invites applications for several tenure-track faculty positions. Although we encourage applications from candidates with strong credentials in any area of molecular biology, we are especially interested in applicants who propose to study regulation of gene expression, or molecular biological aspects of biology or immunology. Experience in recombinant DNA techniques is desirable. These appointments provide excellent opportunities to develop independent research and teaching programs in an expanding medical school department. Send curriculum vitae, a statement of research and teaching interests and the names of four references to Dr Fritz Rottman, Chairman, Department of Microbiology, Case Western Reserve University Cleveland, Ohio 44106. An Equal Opportunity/Affirmative Action Employer

(NW081)A

## **POST-DOCTORAL RESEARCH ASSOCIATES**

Positions are available immediately to work in the area of internalization and intracellular binding of yona dotropins and prostaglandins in corpora lutea. Candidates with experience in one or more of the following areas will be considered: subcellular fractionation; marker enzyme assays; prostaglandin biosynthesis and metabolism; membrane receptors; cell dispersions; cell and tissue culture. Send curriculum vitae and three letters of recommendation to: Dr. Ch. V. Rao, Dept. of OB/GYN, 436B MDR Bldg, University of Louisville, Louisville, KY. 40292. (NW075)A

## **UNIVERSITY OF** THE WEST INDIES

Trinidad

Applications are invited for the post of

## SENIOR LECTURER/ LECTURER IN **BIO-CHEMISTRY**

in the Department of Biological Sciences. Candidates should hold a good honours first degree in a bio-logical subject and postgraduate qualifications in Biochemistry. Research and teaching experience in plant biochemistry, microbiology or nutrition is desirable.

Salary Scale (to be reviewed): Senior Lecturer TT\$38,616 to TT\$49,092 pa; Lecturer TT\$29,784 to TT\$43,752 pa (£1 sterling = TT\$4.41). FSSU. Unfurnished accommodation or housing allowance. Family passages. Study and Travel Grant.

Detailed applications (2 copies), including a curriculum vitae and naming 3 referees, should be sent as soon as possible to the Secretary, University of the West Indies, St Augustine, Trinidad.

Applicants resident in UK should also send 1 copy to the Committee for International Cooperation in Higher Education, The British Council, Higher Education Division, 90/91 Tottenham Court Road, London WIP ODT. Further details are available from either address. (9902)A

## POSTDOCTORAL POSITION

available January 1982 for 1 or 2 years. Research on intestinal absorption and metabolism of toxic metal ions. Biochemical and/or physiological training required and experience with absorption techniques desirable. Starting salary: about \$14,000. Send curriculum vitae and three letters of recommendation to: Dr. Robert H. Wasserman, Department of Physiology, New York State College of Veterinary Medicine, Cornell University, Ithaca, New York 14853. An Equal Opportunity/Affirmative (NW074)A Action Employer.

## **POSTDOCTORAL** RESEARCH POSITION

Two postdoctoral positions (post graduate research, 1-3 years) available January 1, 1982, for Plant Biochemist to study the Development of choloroplast thylakoids. Experience in organelle isolation, electrothoresis, lipid analysis, and/or enzymology preferred. Applications should be received by December 15, 1981. Salary \$15,936 to \$19,848.

Send curriculum vitae to: Dr N Terry, Department: Plant and Soil Biology, 108 Hilgard Hall, University of California, Berkeley, California 94720. The University of California is an Equal Opportunity/ Affirmative Action Employer. (NW085)A

## HIGH ALTITUDE **OBSERVATORY**

Visitor Appointments at the High Altitude Observatory are available for new and established PhD's for up to one year periods to carry out research in solar physics, solar terrestrial physics, and related subjects. Applicants should provide a curriculum vitae including education, work experience, publica-tions, the names of three scientists familiar with their work, and a statement of their research plans. Applications must be received by 15 January 1982, and they should be sent to: Visitor Committee, High Altitude Observatory, National Center for Atmospheric Research (NCAR), PO Box 3000, Boulder, Colorado 80307, NCAR is an Equal Opportunity/Affirmative Action (NW931)A Employer.

## ORGANIC CHEMIST

## **ANTIBIOTICS • ISOLATION** CHARACTERIZATION

SmithKline Corporation, a diversified multinational health care firm located in Philadelphia, Pennsylvania, is seeking an Organic Chemist for its suburban Philadelphia facility who:

- is able to isolate and characterize a variety of biologically active compounds from fermentation sources and other natural sources.
- can develop methods for detecting and isolating these
- can supervise a group in isolation and structure determination work.

Requirements include:

- PhD in organic chemistry with demonstrated post doctoral or industrial competence in isolation/characterization and
- structure determination.
  strong background in modern instrumental techniques including: HPLC, IR, UV, CMR, PMR, and MS. experience and desire to work at the bench with small and sensitive samples.
- ability and interest to participate in research planning with an interdisciplinary group of scientists.

SmithKline offers an excellent compensation and benefits package along with opportunity for personal and professional growth. Please forward your resume, in confidence, to: W.B. Flagg, Senior Employment Administrator, SMITHKLINE CORPORATION, 1572 Spring Garden Street, Philadelphia, PA 19101.

(NW070)A

We are an equal opportunity employer M/F/H/V

## **Rhizobiologists**

Agrigenetics Corporation is a broadly-based plant science company engaged in research and in the development, production conditioning and marketing of genetically-improved seed of more than 50 crop species and a variety of rhizobacterial inoculant

Opportunities now exist for several scientists (Ph.D. or MS.) to join the microbiology section of the Advanced Research Laboratory at Madison, Wisconsin in the area of Rhizobium genetics. Candidates familiar with the biochemistry and molecular genetics of Rhizobium in respect to symbiotic nitrogen fixation are invited to apply for new positions. Practical experience in working with Rhizobial plasmids and in recombinant DNA technology will be a major factor in the selection of candidates.

Successful applicants will join a group of more than 30 scientists working in various areas of plant molecular and cellular biology in a modern and attractive laboratory. Opportunities exist for interactions with additional Agrigenetics scientists at other locations, as well as the Corporation's applied divisions involved with legume species and in the fermentation and production of inoculants

Please send resume to the Director, Advanced Research Laboratory. Agrigenetics Corporation, 5649 East Buckeye Road, Madison, Wisconsin 53716

(NW073)A

Fisheries Research Laboratory, Lowestoft

Ministry of Agriculture, Fisheries and Food

## **Biologist/ Mathematician**

to assist with research and the application of mathematical modelling techniques for the assessment and management of exploited fish populations. Work will also include the preparataion, amendment and operation of computer programs and the supervision of junior staff.

Candidates, normally aged under 27, should have an honours degree equivalent in biology or mathematics.

Final year students will not be considered

Appointment as Scientific Officer £5,175-£6,960 with starting salary according to qualifications and experience.

For further details and an application form (to be returned by 11 December 1981) write to Civil Service Commission, Alencon Link, Basingstoke, Hants RG21 1JB or telephone Basingstoke (0256) 68551 (answering service operates outside

office hours. Please quote ref: SB/67/AD.

## <u>Scienti</u>

## Wanted writers for Indian Magazine

Those interested in promoting scientific matters in the third world are welcome to write features and reports on current scientific topics of general interest for the forthcoming fortnightly, Science Goodnews. Subscription price: £15 or \$20 including air postage. Write to: Ms. A. Sultana, 1 Chah Kanker, Victoria Street, Lucknow-226003, India. (W507)A

## Griffith University -**Brisbane Australia**

School of Australian Environmental Studies

The School stresses a multi-disciplinary and problem-oriented approach to undergraduates and postgraduate-teaching and research. It is committed to a number of broadly based field investigations of major issues.

## Lecturer — Ecology Salary range \$A19 821 - \$A26 037

The School has a vacancy for a lecturer with teaching and research experience in one or more of the following areas —:
Community, Population or Physiological Ecology of Vertebrates

The appointee will be required to teach in the Ecology and basic Biology components of the School's undergraduate programme. Duties will also include research and the supervision of postgraduate students in appropriate fields.

The appointee should be committed to inter-disciplinary teaching and research in a School community with a wide range of backgrounds and interests. An intending applicant will be expected to have a PhD degree. Demonstrated interests in such areas as wildlife management, conservation and the interactions between people and their environment would be advantageous. A first-hand knowledge of the Australian environment is preferred.

The position will be available from 1 July, 1982. It is offered as a continuing appointment with the expectation of tenure after the completion of an initial three year period.

Applications, including curriculum vitae and the names of three referees, and requests for further details about the position should be addressed to the School Administrator. School of Australian Environmental Studies, Griffith University,

NATHAN Q 4111, AUSTRALIA TELEPHONE — (07) 275 7427 The closing date for applications is Friday 1 January, 1982.

## **FELLOWSHIPS**

## IMPERIAL CANCER RESEARCH FUND

**DEVELOPMENTAL GENETICS** LABORATORY (MILL HILL)

## **POSTDOCTORAL** RESEARCH FELLOWSHIP

Applications are invited for a three year postdoctoral appointment, starting September 1982, to work on the molecular genetics of pattern for-mation in *Drosophila*. The project involves the study of genes affecting the establishment of early embryonic pattern. The work makes use of recombinant DNA technology, genetic analysis and embryology, and experience of one of these techniques would be useful although not essential.

Salary range £7,700 to £9,750 plus Outer London Weighting (rate under review) with entry according to qualifications and length of post-doctoral experience.

For further information contact Dr D Ish-Horowicz at ICRF, Burtonhole Lane, Mill Hill, London NW7. Applications supported by full typescript CV, including date PhD obtained, list of publications and names and adresses of two referees, should be sent to the Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2 by 31st December 1981 quoting reference

## MOLECULAR CELL **BIOLOGY PREDOCTORAL FELLOWSHIPS**

The Graduate Program in Molecular Cell Biology invites applications from highly qualified students interested in interdisciplinary PhD program. Major areas of emphasis include animal virology, bacterial and somatic cell genetics, cancer biology, cellular immunology and immunochemistry, connective tissue and protein biochemistry, infectious diseases and host defense, membrane biochemistry, nucleic acid synthesis, and research involving the cause and prevention of dental caries.

All students admitted to the program receive stipends of \$6,300 plus tuition and fees per year. After admission to candidacy the stipend is increased to \$7,000 per year.

Contact: Dr Roy Curtiss III, Director of Molecular Cell Biology Graduate Program, Department of Microbiology, University of Alabama in Birmingham, Birmingham, Alabama 35294. (NW078)E

## UNIVERSITY **OF SUSSEX** School of Biological Sciences

**POSTDOCTORAL** RESEARCH FELLOW

Applications are invited for a research fellowship to work on a project to isolate, clone and characterise the origins of DNA repliction from eukaryotic cells (see Expt. 1 Cell Res 129 (1980) 211-221; Nature, 284 (1980) 185-187). Experience in DNA recombinant techniques would be a great advantage. The project is for one year in the first instance. Salary on the scale for Research Fellow Grade 1A £6,070 to £10,575 pa.

Further particulars may be obtained from Professor Sydney Shall, Cell & Molecular Biology Laboratory, Biology Building, University of Sussex, Brighton, East Sussex BN1 9QG, to whom applications, including academic record, recent research work, a list of publications and the names of three referees, should be submitted to arrive no later than 31 January 1982. (9901)E

## **GRANTS** and **SCHOLARSHIPS**

## **UNIVERSITY OF** WESTERN AUSTRALIA Perth FORESTS DEPARTMENT **POSTGRADUATE SCHOLARSHIP**

Applications are invited from graduates with a first-class or upper division second-class honours degree in Botany, and Forestry or Agriculture graduates whose courses of study have extended over at least four years. The Scholarship, financed by the Forests Department of Western Australia, will be tenable for up to three years in the Department of Botany of the University, and is valued at \$A4,620 per annum; an additional dependants' allowance of \$A2,220.40 for wife, and \$A520 per child is available per annum.

The scholar will be required to undertake research for a PhD degree in one of three areas: (a) the biology of short-lived legumes which occur after fire in the jarrah forest, (b) the biology of an understorey tree, Banksia; (c) analysing reasons for the poor survival of Pinus seedlings after planting in old plantations. Other possible projects in forest ecology may be approved in consultation with the Department of Botany and the Forests Department of Western Australia.

Further information is available from the Head of the Department of Botany.

Applications in triplicate stating personal particulars, academic record, research experience, and other relevant information, should reach the Registrar, The University of Western Australia, Nedlands, Western Australia 6009, by 18 December 1981. Candidates should request two academic referees to write immediately to the Registrar.

## CONFERENCES and COURSES

## **EMBO PRACTICAL COURSE**

## **Automated Chemical and Enzymic** Gene Synthesis

Department of Biochemistry Technische Hochschule Darmstadt

## MARCH 21st TO APRIL 3rd, 1982

The teaching staff will include:
J.H. van Boom (Leiden), M.H. Caruthers (Colorado), H.J. Fritz (Köln), M.J. Gait (Cambridge, UK), H.G. Gassen (Darmstadt), W. Hillen (Darmstadt), K. Itakura (City of Hope, LA), H. Kossel (Freiburg), H. Köster (Hamburg), K.E. Norris (Bagsvaerd), E. Ohtsuka (Osaka), H. Schott (Tübingen), H. Selinger (Ulm), O.C. Uhlenbeck (Urbana), E.L. Winnacker (München) and others.

The programme will consist of practical work, lectures and seminars on

- solid-phase chemical synthesis of oligodeoxynucleotides
- phosphotriester method as related to the phosphoroamidite procedure
- automated oligonucleotide synthesis
- oligonucleotides from DNA fragmentation
- enzymic ligation of oligonucleotides
- recombination of RNA
- survey of oligonucleotide separation and analysis
- ligation of synthetic genes (promotors) to plasmid vectors

A maximum of 15 students will be accepted. Applications should include a short curriculum vitae and a description of present research interets. The registration fee for the practical course is 200, DM, which does not include food and lodging. A small number of grants in aid to cover partially board and lodging expenses may be granted to participants who are unable to obtain funds from other sources.

The weekend MARCH 27/28th will be kept free from practical work to allow the participation in a WORKSHOP entitled

## **Prospects of Automation in** Gene Synthesis

Informal application is sufficient for the workshop. The number of participants will be limited to 100. The registration fee is 60, DM.

## THE CLOSING DATE FOR APPLICATIONS IS JANUARY 15th.

Those accepted will be notified not later than January 31st, 1982. Applications should be sent to Dr H.G. Gassen, T H Darmstadt, Institut für Organische Chemie und Biochemie, Petersenstrasse 22, D-6100 Darmstadt. Phone: 06151/163657, Telex: THD 419579 (W504)C

## 3rd INTERNATIONAL **CONFERENCE ON BIOLOGY** OF VERTEBRATE AND **INVERTEBRATE SKIN**

of European Society for Comparative Skin Biology, in Krakow on 6-10 September, 1982. Details from Prof. M. Jakubowski, Dept. of Comparative Anatomy, Jagellonian University, ul. Karasia Krakow, Poland. (9895)C

## FRIEDRICH MIESCHER-INSTITUT Basel **POSTDOCTORAL FELLOWSHIP**

is available from the beginning of 1982 (or later). The general topic is the structure, function and regulation of eukaryotic genes by steroid hormones. Emphasis is on the isolation, cloning, characterization, in vitro construction of mutants, in vitro and in vivo expression of cloned genes. Candidates should be experienced in the techniques of nucleic acid biochemistry and cloning. Applications (with curri-culum vitae) should be sent to Dr J-P Jost, Friedrich Miescher-Institut, P.O. Box 273, CH-4002 Basel, Switzerland.

NATO Advanced Study Institute Course on:

## GENETIC ENGINEERING IN EUKARYOTES

July 26 through August 6, 1982 **Washington State University** Pullman, Washington

Topics will include DNA transformation in fungi, mammalian cells and plant cells. Emphasis on development of vectors for gene transfer and expression in eukaryotes. Selection and biochemical characterization of eukaryotic mutants useful for transformation experiments. A proceedings will be published.

Participants will be limited to 85 and should be at least of postdoctoral level. There are a limited number of fellowships available.

Advisory Committee: E. C. Cocking, University of Nottingham, UK; O. W. McBride, NIH, Bethesda, MD, USA; E. W. Nester, University of Washington, Seattle, WA, USA; and J. Schell, University of Ghent, Belgium.

Organizing Committee: P. F. Lurquin, A. Kleinhofs, and W. A. Becker, Washington State University, Pullman, WA, USA.

Send inquiries to: NATO Advanced Study Institute, Conference Office, 323 Agricultural Sciences Building, Washington State University Pullman, Washington 99164.

## MSc IN MEDICAL MICROBIOLOGY

(FULL-TIME OR PART-TIME)

Advanced academic and practical training in bacteriology, virology, immunology, mycology, microbial genetics and medical parasitology as applied to clinical and preventive medicine is provided through an inter-collegiate course of study extending over one year of FULL-TIME study, or by PART-TIME study over two, three of four years by the accumulation of credits.

The course is open to medical, dental and veterinary practioners, graduates in science or pharmacy or other suitably qualified students. Candidates will normally be required to have at least one year's practical experience of Medical Microbiology.

Exemption from the Primary Examination for the MRC Path may be granted to suitably qualified British subjects resident in the United Kingdom taking the full-time course or the part-time course by the accumulation of credits. Closing date for applications 1 March 1982.

Further particulars from the Registrar, London School of Hygiene and Tropical Medicine, Keppel Street, London WC1E7HT. (9896)C

## **STUDENTSHIPS**

## UNIVERSITY OF ABERDEEN DEPARTMENT OF ANATOMY

BRITISH DIABETIC ASSOCIATION STUDENTSHIP

Applications are invited from suitably qualified candidates for a PhD Studentship provided by the British Diabetic Association for the study of peripheral nerve structure in experimental diabetic rats and genetically diabetic mice. The research will be conducted in the Department of Anatomy. The Studentship is tenable for three years from January 1982.

Further information from, and applications to, Dr A K Sharma, Department of Anatomy, University of Aberdeen, Marischal College, Aberdeen AB9 1AS (Telephone 0224 40241, Ext 237 or 233). Applications must be accompanied by the names of two references.

## **ANNOUNCEMENT AND CALL FOR PAPERS**

International Symposium on the Biomedical Effects of Ozone and Related Photochemical Oxidants March 14-18, Pinehurst, NC

Objective:

Ozone and related oxidants are a problem of increasing concern because of their potential for effects on human health. The objective of this symposium is to update the database on the biomedical effects of ozone and related oxidants of photochemical smog.

Symposium Program:

The program will contain seven sessions with up to five invited presentations and discussion by an invited panel. Volunteer contributions will be presented in poster sessions. The following topics will be included: atmospheric chemistry; biochemical and morphological responses and effects on pulmonary function in experimental animals and humans; effects of chronic exposures; post-exposure susceptibility to infection; and modifying factors.

Symposium co-chairmen are M.G. Mustafa and R.S. Bhatnagar. The session chairmen, listed alphabetically, are: A.P. Altschuller, R.S. Bhatnagar, D.L. Dungsworth, M.J. Evans, L.J. Folinsbee, R. Frank, D.E. Gardner, B.D. Goldstein, E. Goldstein, J.D.Hackney, J. Mead, M.A. Mehiman, D.B. Menzel, J. O'Neil, R.P. Sherwin and D.F. Tierney.

Symposium proceedings will be published incorporating peer-reviewed manuscripts.

Closing Date for Papers:

January 1, 1982.

For submitting abstracts and for registration and program information contact:

Institute for Biomedical and Environmental Studies, Inc. 2040 Pioneer Court, Suite 15, San Mateo, CA 94403

## THE QUEEN'S UNIVERSITY OF BELFAST

## SERC RESEARCH STUDENTSHIPS 1982

The Science and Engineering Research Council is likely to offer to suitable candidates a limited number of research studentships for 1982 tenable in the Faculties of Science or Engineering; the former includes the Department of Archaeology, Applied Mathematics and Theoretical Physics, Biochemistry, Botany, Chemistry, Computer Science, Genetics, History and Philosophy of Science, Microbiology, Pharmacy, Psychology, Pure Mathematics, Pure and Applied Physics, Statistics and Operational Research, and Zoology; the latter, Engineering Mathematics, Aeronautical, Civil, Mechanical and Industrial, Electrical and Electronic, and Chemical Engineering Departments.

The value of these awards will be in accordance with SERC scales and students graduating in 1982 in Great Britain (and who are not resident in Northern Ireland) are invited to write stating their particular field of interest to the appropriate Dean, The Queen's University of Belfast, Belfast BT7 1NN, by *I December 1981*, or as soon as possible thereafter. (9899)F

## UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL

DEPARTMENT OF PHYSIOLOGY
AND PHARMACOLOGY

## POSTGRADUATE STUDENI HUMAN MUSCLE PHYSIOLOGY

Applications are invited for thi studentship tenable for 2 years in th first instance. The work concerns th physiology of elderly human muscl and will be supervised by Professo P H Fentem and Dr C T M Davies The Conditions of the studentship will the those applied by the Researci Councils.

Applicants should send thei curriculum vitae and names of academic referees to Professor P F Fentem, Department of Physiolog and Pharmacology, Medical School Queen's Medical Centre, Notting ham NG7 2UH as soon as possible.

## TO ACHIEVE VALUES LIKE THESE IN EIA/ELISA ANALYSES, USE A NUNC-IMMUNO PLATE.

If variations in plate binding capacities have been plaguing your EIA/ELISA results, you need the new Nunc-Immuno Plates!

Nunc-Immuno Plates are specially fabricated to provide high and *uniform* binding combined with excellent optical properties. The result? Minimal variation in the amounts of protein adsorbed, well to well, plate to plate, and minimal optical distortion to assure low background readings in automatic or semi-automatic analyzers. (Nunc-Immuno Plates are compatible with all known analyzers.)

In fact, the Nunc-Immuno I Plates carry a test certificate indicating binding capacity variation and background reading. Our quality criteria include

binding capacity CV less than 5%, with the lowest well capacity within 10% from mean, and background reading on all wells within +/-0.005 absorbance units from mean.

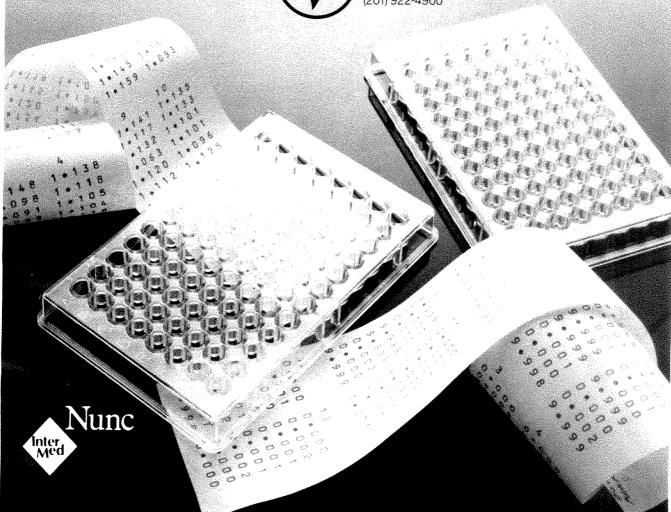

We also offer the Nunc-Immuno II Plate for use where accuracy and reproducibility are not quite as critical, but budget is. Same quality fabrication, but without individual test certification.

Try the new Nunc-Immuno Plates on your own EIA or ELISA analyses. Call or write today for a free sample—your results will convince you. Manufactured by Nunc,

Denmark and marketed in the U.S. by Vangard International.

# The fraction collector that turns science fiction into science

Just a few years ago no one would have believed that a fraction collector like SuperRac could exist. Most researchers were used to their constant-volume and constant-time collectors – with level-sensors at best.

Many were resigned to a compromise between resolution and the efficient use of collection vessels.

SuperRac will change all that.

To begin with, SuperRac has built-in slope detection. Unlike a simple level sensor, it cuts peaks at their true beginnings and ends. You can even collect unresolved peaks in well-resolved fractions . . . and you never need to worry about baseline drift.

SuperRac also diverts uninteresting eluate to a waste trough - via a valve -

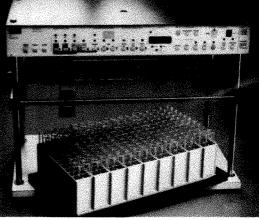

so you use fewer test tubes.

SuperRac's memory stores five different collection procedures that you can recall at the touch of a button. It has nine time windows allowing you to limit collection to interesting parts of your chromatogram.

SuperRac automatically compensates for asymmetric peaks and peak-width broadening during an isocratic elution. And it continues to run the pump for a specified time after a collection to clean and equilibrate the system.

Ask your local LKB distributor for more information on the new SuperRac. He'll give you several more reasons why we named it Super.

New SuperRac

# Defined Sequence Oligodeoxynucleotides

## Easy synthesis in your own lab

Now construct oligodeoxynucleotides easily and economically using the soluble triester synthesis method and reagents from P-L Biochemicals.

P-L's reagents help you reduce synthesis time and costs with easier, faster synthesis right in your own laboratory. Plus, you get cleaner reactions, easier purification procedures and higher yields.

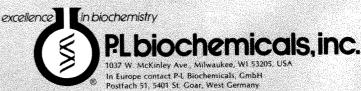

P-L has all the reagents you need in stock for prompt delivery.

- Barium salts of the 4 protected deoxynucleoside 3'-chlorophenylphosphates.
- 4 protected deoxynucleosides for 3'-termination.
- 16 protected deoxydinucleotides for speedier block addition.
- 16 protected 3'-terminating deoxydinucleotides.
- N<sup>4</sup>, 2<sup>7</sup>, 3<sup>7</sup>-Tribenzoyl cytidine for terminating your synthetic oligodeoxynucleotide with a 3<sup>7</sup>-phosphate.
- · Condensing reagents.

## Rapid Custom Synthesis

P-L Biochemicals will synthesize oligodeoxynucleotides at low cost...from 50 μg (about one A<sub>260</sub> unit) to grams. We use only highly purified reagents throughout. The sequence of your oligodeoxynucleotide is proven by established techniques. The complete absence of blocking groups is proven by exhaustive enzymatic hydrolysis and examination of the component nucleosides. Call Dr. Bill Gette today at (414) 347-7384 to discuss your needs and request a quote. You will be pleased at the low cost of our custom synthesis.

Whether you choose to synthesize your own oligodeoxynucleotides or have us prepare them for you, rely on P-L Biochemicals' 30 years of experience in nucleic acid chemistry for reliability, quality and economy.

At the push of a button, in your own lab, you can produce sequences of DNA with BIO LOGICALS' fully automated DNA/RNA Synthesizer. You can synthesize sequences of up to 20 bases in length in ess than 10 hours. No longer will your experiments be limited by the availability of probes, primers, promoters and other sequences.

Everything you need to produce oligonucleotides is available in one package. All bases and reagents are prepared and prepacked. You simply connect two manifolds to the instrument, program your sequence and the DNA/RNA Synthesizer makes it automatically without error.

You have heard and read about the new 'gene machines'. The only fully automated DNA/RNA Synthesizer is available now from BIO LOGICALS. Our instrument employs proprietary state-of-the-art phosphite triester chemistry.

Our DNA/RNA Synthesizer is reliable. To back that up: if your instrument is down during its one year warranty period we will deliver sequences to you for just the price of the reagents.

SAME DAY DNA!

## Hybri-Dot\*

#### For low cost, time-saving hybridization to "dots" of target DNA and RNA

BRL has designed a 96 well manifold that simplifies scale-up of the sensitive "dot hybridization" procedure for detection of specific DNA and RNA sequences. In this procedure, as little as one picogram of a specific nucleic acid sequence, bound to nitrocellulose as a small spot, can be detected using  $^{32}\text{P-labeled probe}~(\sim 10^8\text{dpm}/\mu\text{g}).$  Dot hybridization has been used to detect viral DNA in lymphocytes and in serum.

The 3 mm diameter sample wells of the BRL® Hybri●Dot™ System are arranged to precisely match the array of a standard 96-well microtitration plate. This simplifies and accelerates procedures such as the large-scale screening of bacterial colonies for recombinant plasmids.

**BRL No. 1050MM** 

#### **Features**

#### • 96-Well Design Compatible with "Microtitration" Plates

Conveniently adapts to protocols using 96-well plates. Avoids time consuming tube handling and labeling.

#### • 3 mm Diameter "Spot"

Readily detects picogram quantities of nucleic acids hybridized to low levels of radioactive probe for conservation of valuable reagents.

#### Pre-cut, Indexed Nitrocellulose Sheets

Each Hybri®Dot™ System includes ten sheets of pre-cut nitrocellulose. Notched corners assure accurate reference afterremoval from the system.

#### Easy-to-Assemble, Precision Design

Unique, precision milled surfaces assure a secure, fluid-tight seal without gaskets, Orings or special tools.

BRL welcomes all questions concerning the performance of the Hybri•Dot™ System. Ask for a BRL Technical Services Representative at (800) 638-4045. To place an order, contact Customer Services Department at (800) 638-8992.

#### Voyager 1 at Saturn

The new results from Voyager 1, which appeared in Nature of 20 August are now available in a glossy, 88-page booklet.

Copies can be ordered from the Nature offices in London, Basingstoke and New York at the following prices (including postage):

UK £2.00 each; USA & Canada US \$4.00; Rest of World £2.50 (surface), £3.50 (air)

Payment should accompany orders and may be in any currency at the prevailing exchange rate. Cheques should be made payable to Nature.

#### JIDE TO AU

Authors should be aware of the diversity of Nature's readership and should strive to be as widely understood as possible.

Review articles should be accessible to the whole readership. Most are commissioned, but unsolicited reviews are welcome (in which case prior consultation with the office is desirable).

Scientific articles are research reports whose conclusions are of general interest or which represent substantial advances of understanding. The text should not exceed 3,000 words and six displayed items (figures plus tables). The article should include an abstract of about 50 words.

Letters to Nature are ordinarily 1,000 words long with no more than four displayed items. The first paragraph (not exceeding 150 words) should say what the letter is about, why the study it reports was undertaken and what the conclusions are.

Matters arising are brief comments (up to 500 words) on articles and letters recently published in Nature. The originator of a Matters Arising contribution should initially send his manuscript to the author of the original paper and both parties should, wherever possible, agree on what is to be submitted

Manuscripts may be submitted either to London or New York (decisions being made only in London). Manuscripts should be typed (double spacing) on one side of the paper only. Three copies are required, each accompanied by copies of lettered artwork. No title should exceed 80 characters in length. Reference lists, figure legends, etc. should be on separate sheets, all of which should be numbered. Abbreviations, symbols, units, etc. should be identified on one copy of the manuscript at their first appearance.

References should appear sequentially indicated by superscripts in the text and should be abbreviated according to the World List of Scientific Periodicals, fourth edition (Butterworth 1963-65). The first and last page numbers of each reference should be cited. References to books should clearly indicate the publisher and the date and place of publication. Unpublished articles should not be formally referred to unless accepted or submitted for publication, but may be mentioned in the text.

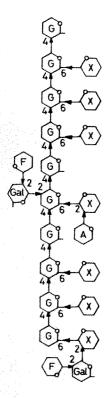

Each piece of artwork should be clearly marked with the author's name and the figure number. Original artwork should be unlettered. Suggestions for cover illustrations are welcome. Original artwork (and one copy of the manuscript) will be returned when manuscripts cannot be published.

Requests for permission to reproduce material from Nature should be accompanied by a self-addressed (and, in the case of the UK and USA, stamped) envelope.

### N-w su.fac-s for c-ll cultur-

Now you can choose the most suitable microcarrier for your culture

Cytodex microcarriers bring new opportunities to

routine and experimental cell culture

production of viruses, interferon and other cell products

• in vitro studies on differentiation and metabolism

Cytodex 1

The microcarrier proven to be effective for growing more than 100 different cell types.

Especially developed for better yields of viruses and cell products. Retains all the advantages of Cytodex 1 with the added benefit of new charged groups necessary for cell attachment localized only

on the surface of the microcarriers.

**Cytodex 3** The latest concept in microcarriers. The stable collagen surface gives improved attachment and yields of many cell types, especially those normally difficult to grow in culture. Enzyme digestion of the surface gives improved recovery and viability of harvested cells.

Make the most of your cell cultures. For more information on how Cytodex microcarriers give you new opportunities in cell culture contact us today.

## **ULTROPHOR**

Put wavy bands where they belong. Among yesterday's problems.

Banish wavy bands with Ultrophor, a unique new instrument designed exclusively for professional electrofocusers by LKB, electrofocusing pioneers since 1960.

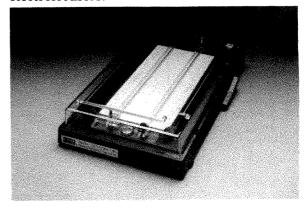

The ultracompact Ultrophor will cope with any analytical or preparative electrofocusing situation thanks to its radically new approach to electrode design, the construction of the highly efficient glass/aluminum cooling plate and the opportunity for atmospheric control.

The impressive list of bonuses include the flexibility of being able to run gels of any length up to 26 cm long or gels of any thickness, especially capillary-cast ultrathin gels, with less chance of wavy or skewed bands. The Ultrophor also has an unmatched capability to run high pH gels for sharp separations of alkaline samples as well as handle oxygensensitive or other labile samples.

Not only do you save valuable lab space with the compact Ultrophor but you save on time too because it's so fast and convenient to use and super-easy to clean. Like all LKB units, the new Ultrophor boasts a complete backup system and comprehensive technical support.

Contact your nearest LKB representative today for full information.

Ultrophor – the straight choice for professional electrofocusers.

## LINK UP WITH BIOSEARCH

#### OLIGONUCLEOTIDE SYNTHESIZER

BIOSEARCH introduces the Synthesis Automation Module (SAM) for automated synthesis of DNA and RNA. The SAM is an extremely versatile automated synthesizer which easily attaches to existing HPLC's, enabling the rapid and inexpensive synthesis of nucleotides as well as polypeptides.

#### Simplicity

The SAM is easily connected to an HPLC and supplied with reagents in top-mounted reservoirs. Removal of the finished product and reconversion of the HPLC to an analytical instrument is accomplished in minutes.

#### Service

**BIOSEARCH** offers:

- · A course in nucleotide synthesis
- · 6 months warranty on all parts and labor
- Complete technological support for nucleotide synthesis, purification and sequencing
- A complete line of reagents for nucleotide synthesis

The SAM has the following features:

#### Microprocessor Control

The custom built microprocessor has a 500 step memory incorporating 16 outputs, 4 inputs and a 12 digit alphanumeric LED display.

#### Versatility

All current and emerging nucleotide synthesis methodologies may be employed, including the popular phosphite and phosphotriester chemistries. The SAM may also be quickly adapted to peptide synthesis as well as any number of new chemistries.

#### **Custom Programming**

Nine user-defined programs may be stored in the machine. The SAM is shipped preprogrammed to perform oligonucleotide synthesis by the phosphite method. Peptide synthesis programs will also be supplied.

#### Complete Automation

All steps of the synthesis of the oligonucleotides are performed automatically by the module. The phosphite method cycle time is 30 minutes.

#### CUSTOM SYNTHESIS OF OLIGONUCLEOTIDES

Because of recent technological advances in the automated synthesis of nucleotides, BIOSEARCH is able to offer the rapid and accurate synthesis of custom oligonucleotides.

Length of nucleotide	\$/1 OD
4	600
6	800

## The Biochemists' Songbook

Professor HAROLD BAUM Foreword by Professor Sir Hans Krebs

A collection of highly original and entertaining songs compiled by perhaps the world's leading exponent of the biochemical ballad. Set to such famous tunes as 'Waltzing Maltida', 'The British Grenadiers' and 'Men of Harlech' the

pathways take on a completely new meaning to researchers and hard-pressed students alike Each song is accompanied by music arranged for voice and piano and the appropriate biochemical pathway displayed in a more conventional form.

## British Journal of CLINICAL PHARMACOLOG

ESSENTIAL INFORMATION AT YOUR FINGERTIPS. EVERY MONTH!

Published monthly on behalf of the British Pharmacological Society, British Journal of Clinical Pharmacology is as fast-moving as the area of science it examines:

Bridging the gap between medical professions, clinical research and the pharmaceutical industry. Containing papers and reports on all aspects of drug action in man, in both health and disease. Providing free copies of the proceedings of selected symposia on new methods, new drugs and new approaches to treatment, to all subscribers.

To keep up-to-date in this fast-moving area of science why not join the ever-increasing number of clinical pharmacologists all over the world who rely on the British Journal of Clinical Pharmacology as their professional journal.

#### **ANNUAL SUBSCRIPTIONS**

UK £75.00 **USA/Canada US\$185** Rest of the world £89

Orders should be accompanied by remittance, cheques made payable to Macmillan Journals Ltd: Subscription Department, Brunel Road, Basingstoke, Hampshire, RG21 2XS, England.

Sample copies are also available from the same address.

## Ortho offers unexcelled systems for immunobiology researchers

LYMPHOCYTES

MONOCYTES

Three major subpopulations of white cells by forward and 90° light scatter measurements of whole blood (RBC lysis only). Using Ortho-mune Monoclonal Antibodies, gating on the lymphocyte population, human peripheral T lymphocytes (OKT3\* cells) can be quantitated and/or sorted.

GRANULOCYTES

it can perform rapid
multiparameter sort
decisions while simultaneously providing complete
statistical data analysis. This
capability provides significantly
higher throughput and increased
sorting efficiency.

Wide Applicability

The system has proved extremely valuable in cell-antigen and tumor studies. It can also be

employed for research into cell sizing, DNA and chromosome analysis and many aspects of cell kinetics and microbiology. The exceptional versatility of the system allows it to keep pace with the researcher's interests, never to limit them.

in cen-anugen

OKT3 POSITIVE

90° SCATTER

Ortho Diagnostic Systems has established a firm leadership position in cell sorting and analysis instrumentation—in fact, acceptance of Ortho systems by the scientific community has been so great that these instruments now are considered the standard of performance in the field.

#### Versatile Instrumentation

The Ortho Cytofluorograf\* Government is an example of that leadership and commitment to research. As the only flow cytometer to offer a choice of five lasers, (including two installed as standard), the Cytofluorograf provides

exceptional applications flexibility.

Flexibility is enhanced further by a modular design which allows the system to be upgraded as research needs change. Performance too is outstanding with analysis rates of up to 10,000 cells per second. And only Cytofluorograf offers direct measurement of seven optical parameters including axial light loss, a valuable technique that allows the use of non-fluorescent stains.

The new 2150 Computer and software can acquire up to 16 histograms and simultaneously display any four of these, all in real-time, allowing the operator complete control over all aspects of the experiment. Because 2150 has two independent microprocessors,

Green Fluorescence

**Total Professional Support** 

Ortho's interest in cellular biology extends beyond producing instrumentation. For example, Ortho has developed Ortho-mune\* monoclonal antibodies, the first panel (for research use only) of murine monoclonal antibodies reactive with human T lymphocytes. The company maintains well-equipped applications and training laboratories to develop new techniques and to provide consultative services for customers.

The results of these investigations and others are published in Protocols so that other researchers may share the results. Free copies are available by con-

tacting Ortho.

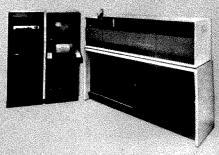

Ask about the Cytofluorograf Flow Cytometer, 2150 and the complete range of Ortho services. Contact Ortho Diagnostic Systems Inc., Research Instruments Division, 410 University Avenue, Westwood, MA 02090 (617) 329-6100.

## How to break the 32P habit and regain control of your schedule.

#### 35S-Nucleotides ATPYS GTPYS JATPlphaS ATPlphaS

The traditional probe for nucleic acid studies has been 32P, one good reason being its high initial specific activity. However, within a short time that advantage dissipates because of 32P's short half life, and the benefits of using 35S in the first place become very persuasive.

To take advantage of these benefits, NEN has developed 35S-nucleotides for nucleic acid studies. Primarily they introduce versatility and convenience compared to <sup>32</sup>P. They also reduce waste and involve the user with less radiation exposure.

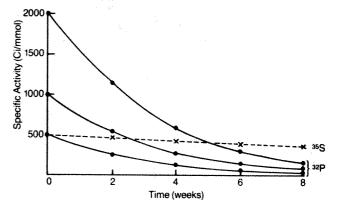

**Biological activity** – These nucleotides have phosphate replaced by  $^{35}$ S-thiophosphate in the  $\alpha$  or  $\gamma$  position. They are biologically active and each may be substituted freely for its natural analog with a variety of enzymes (DNA or RNA polymerase, protein kinase, etc.). However, these compounds and probes prepared from them are resistant to phosphatases and nucleases at the point of thiophosphate substitution, making possible new experiments and techniques.

Longer lived probes - Since 35S has six times the half life of <sup>32</sup>P (87 vs. 14 days), you'll need to make your labeled probes much less often, leaving yourself more time for research. Also there'll be less waste and less expense.

High specific activity - All 35S-nucleotides are available from NEN at specific activities approaching 500Ci/mmol. Even more important, the useful specific activity will be maintained longer by nucleic acids and proteins because of 35S's longer half life (see diagram).

Freedom from production schedules—NEN's 35Snucleotides are always available from stock. No more planning your work around somebody else's production schedule.

**Economy** – You'll pay no more for the <sup>35</sup>S compounds than for their 32P equivalents. When you count this saving in with the time- and waste-saving advantages described above, you get a powerful argument for making the switch.

Adenosine 5'-( $\gamma$ -thio) triphosphate, [35S]-

NEG-027H 250-500Ci/mmol 15-60Ci/mmol NEG-027

Guanosine 5'-( $\gamma$ -thio) triphosphate, [35S]-

NEG-030H 250-500Ci/mmol 15-60Ci/mmol

Adenosine 5'-( $\alpha$ -thio) triphosphate, [35S]-NEG-033H 250-500Ci/mmol

Deoxyadenosine 5'-( $\alpha$ -thio) triphosphate, [35S]-

NEG-034H 250-500Ci/mmol

All compounds are shipped in ethanol: 20mM tricine (pH 7.6), 20mM dithiothreitol, 1:1, in dry ice

#### Free Technical Bulletin

The use of 35S-nucleotide analogs in 5' end labeling, nick translation, and protein kinase studies is described in our technical bulletin, which is yours by circling the readers' service number.

## Nature announces the first wall chart showing how the U.S. runs its science ...shows who makes U.S. science decisions, who gets the money, and how it's spent

If you're involved in making decisions about science, or if you're looking for your share of science funding, you need <a href="Nature">Nature</a>'s new 1981 guide to how the nation spends its science dollars and who controls that money.

Compiled by <u>Nature</u> from literally hundreds of sources, the wall chart offers data on actual dollars spent on science by government agencies, industry, foundations, universities, research and medical centers. <u>The chart lists key U.S. government policy makers</u>, with their addresses and phone numbers.

Most significantly, the chart shows the interlocking relationships within the science, engineering, and medical establishments.

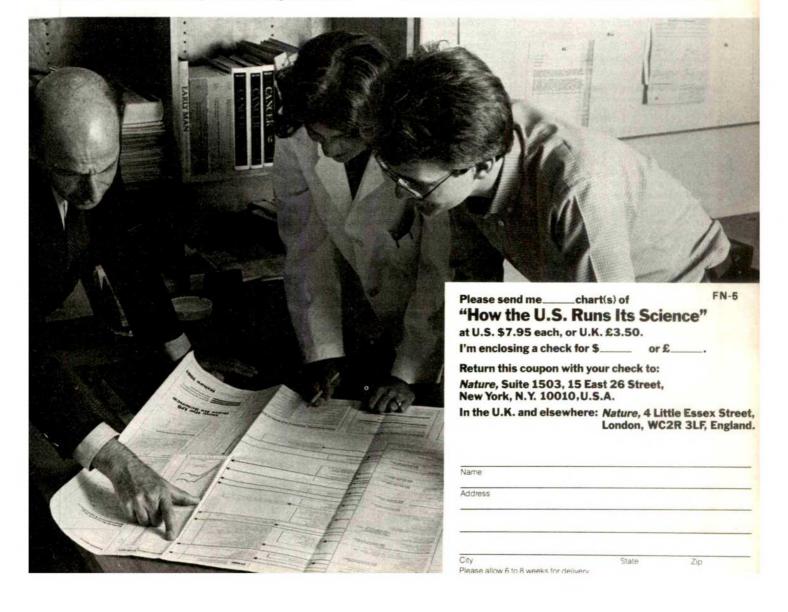

Designed as a fold-out that you can carry to meetings, or for hanging as a 2 x 3 ft. wall poster for permanent reference, the chart enables you to answer questions that

might otherwise take weeks of research to dig out. Compact, color-keyed, and handy, it will be an enormous aid to you and your colleagues. We strongly urge you to order sufficient copies to cover the needs of your entire staff or department.

Toxicology is the study of the reactions, both adverse and compensatory, of living creatures to noxious materials. The hazards to which man is exposed and the manner in which he reacts to them from the moment of conception and thereafter throughout life is the subject of Human Toxicology. This new journal embraces both animal research, where it has a direct significance for man, and studies on man himself. These studies may be biochemical, physiological, pathological, clinical and epidemiological but will all be designed to increase our understanding of the action of noxious substances in the body and of means to counter their effects. All papers will be subject to peer review.

#### EARL L. GREEN

**Director Emeritus of The Jackson** Laboratory, Bar Harbor, Maine. Editor, Biology of the Laboratory Mouse, Second Edition.

Probability and Statistics; Segregation of Alleles; Assortment of Non-Alleles; Linkage, Recombination and Mapping; Mating Systems; Appendix 1 — Mean and Variance of a Binomial Distribution; Appendix 2 — Estimation of a Parameter by the Method of Maximum Likelihood; Appendix 3 — Extensions of the Method of Maximum Likelihood; Appendix 4 — Comparative Efficiency of Matings for Detecting and Measuring Linkage; Appendix 5 — the Fibonacci Sequence; Appendix 7 — Numbers of Mating and Numbers of Mice per Mating; Appendix 8 Probability and Statistics; Segregation of Appendix 7 — Numbers of Mating and Numbers of Mice per Mating; Appendix 8 — Nomenclature; Appendix 9 — Record Keeping; Appendix 10 — Mouseroom Layout and Procedures; Glossary of Signs; Literature Cited; Index

This book is a primer and reference on probability, segregation, assortment, linkage and mating systems for biomedical scientists who breed and use genetically defined laboratory animals for research.

It is organised so as to be useful to 'novices' and 'experts' alike. The former will find an orderly development of the probability aspects of transmission tests, segregation analysis, allelism tests, independence tests, linkage analysis and mapping. They will see how to design genetic experiments to yield data which can be analysed and they will also find a clear exposition of the theoretical consequences of various breeding systems which will enable them to make rational choices as to the kinds of animals to use in their own research.

Experts will find that the most frequently used formulae needed for estimating various genetic parameters and their random sampling variances are assembled in tables or are clearly set forth in the text and that the extensive table of contents and detailed index will enable them to find the necessary formulae quickly.

#### Threats for British academic research

Research councils in the United Kingdom have recently been spared the axe. Is it now about to fall?

Mrs Margaret Thatcher, the British Prime Minister, was proudly telling the Parliamentary and Scientific Committee a year ago that the British government's spending on research had been "protected" from the round of government economies then coming into effect. Will she be able to make the same boast when the government's budget for 1982–83 has been completed? For the past several months, the research councils have been as much concerned with helping British universities out of trouble as with their own affairs. Now, with financial planning for 1982–83 under way, they are alarmed that, next time, the Treasury's finger will point at them.

The research councils have become vulnerable for several reasons, but chiefly because the British government's economic policies have failed. Neither the government nor its supporters can have imagined that it would be embarking on its fourth year in office (next spring) with yet another deflationary budget. By then, the assumption was, the benefits of financial prudence would be sweeping through the British economy. In practice, however, the government failed to implement the controversial but at least novel monetarist policies to which it was committed with anything like the vigour necessary to give them a sporting chance. So the chances are high that the British Treasury will need further reductions of public expenditure in the spring. The research councils are certain to catch its eye.

Two particular arguments will come up, the first of which is the doctrine of equal misery, thoughtlessly used a year ago as the excuse for reducing public support for British universities by 8.5 per cent over three years. In a memorable display of insouciance, the then Secretary of State for Education and Science told the House of Commons that all public institutions must expect to share the burden of financial sacrifice. He was echoed last Wednesday in the House of Commons by his successor, Sir Keith Joseph. Ironically, if the cost of the enforced redundancies among academics now in prospect falls on the government (and there is no other way in which it can be met), the decisions that have been made will not constitute economies at all. The danger now is that the reduction of support for the universities will be used as an argument for cutting back on the budgets of the research councils. For if the research councils exist in part to support academic research, and if the number of academics is to be reduced, it will be argued that research council budgets can be correspondingly reduced.

That argument is a nonsense which betrays a facile ignorance of the upheaval now under way in British universities. Ostensibly at least, the selective allocation of funds by the University Grants Committee in the summer involved an assessment of individual universities' performance in research. At least in theory, casualties among university departments in the next few years are likely to be heaviest among those with an indifferent record in research. On this assumption, the university departments left substantially intact will be just as much in need of research support in the years ahead as in the past. And if the talents of able academic researchers left stranded in moribund departments are not to be wasted (see Nature 19 November, p.198), the research councils will also need funds to help people migrate to centres where promising research can be carried through. What this implies is that the reduction of public subvention for the universities is entirely irrelevant to the needs of the research councils. And any substantial reduction of the councils' capacity

to support academic research will further endanger the health of the British academic research enterprise, already well below par.

Although the budgets of the research councils have been to some extent protected since stagnation set in a decade ago, the protection is far from complete. The cash limits laid down for the present financial year have not adequately compensated for inflation. Meanwhile, the effectiveness of what the research councils can afford to spend in universities is being steadily undermined. With the collapse of the dual support system, by which universities are supposed to provide basic research facilities out of their own funds, the research councils are willy-nilly having to dip into their own pockets for that purpose. At the same time, they are finding that they can no longer fund all the research proposals of high quality that come their way. The Medical Research Council now says so explicitly. But even the pattern of grant applications in the past few years, when the research councils have congratulated themselves that good proposals have been adequately funded, has probably been misleading. Academic research groups, which are not foolish, have for many years been trimming their ambitions to the public knowledge of what the research councils can and will support. The knowledge that proposals that are too ambitious are unlikely to succeed has already contributed to the despondency in the British research community

Even as things are, the condition of the British academic research enterprise gives the lie to the government's claim that research has hitherto been protected. As the infrastructure is eroded, the research councils are compelled to operate on ever thinner ice. Already they have been forced to postpone plans that would in normal times have been considered vitally important the Science and Engineering Research Council, for example, has just put off a plan to break new ground in the fashionable field of molecular electronics. The danger now is that the collapse of morale among academic researchers will be accentuated by the real decline of resources to support their work. The result, quite quickly, could be catastrophic. Even as things are, the government could find that the lack of enterprise and innovation that has brought Britain to its present economic plight will persist even when the long recession comes to an end. To think of further reductions of the research councils' budgets is to behave as if the chance of economic recovery has now vanished. If that is what the government believes, it should say so.

#### Hunger strike's damage

Andrei Sakharov is on hunger strike. Is he right?

Two years of exile in the city of Gork'ii would be enough to drive anybody to despair. So it is forgivable that even courageous spirits such as Andrei Sakharov and his wife Yelena have embarked on a hunger strike to persuade the Soviet government to agree that their son's fiancée, Liza Alexeyeva, should be allowed to join her future husband in the United States. One snag, as the Sakharovs must know, is that their isolation in a remote part of the Soviet Union to which foreign visitors are not allowed will blunt the effect of their protest. Gork'ii is not, after all, Belfast, where the British government obligingly answered questions from the press about the slow progress towards death of the Irish republicans who fatally starved themselves earlier in the

0028-0836/81/480295-02\$01.00 © 1981 Macmillan Journals Ltd

year. The Soviet authorities, on the other hand, will have no such obligation.

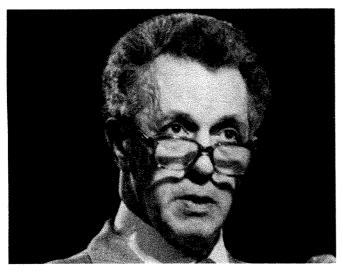

Andrei Sakharov's explanation of his despair is, as always, moving but, on this occasion, strangely unreal. His sense of responsibility derives from having urged his son Alyosha to emigrate when a brief opportunity appeared in 1978, leaving his fiancée behind. (They were later married by proxy in Montana.) But the Soviet authorities are habitually so slow to grant exit visas to citizens wishing to join foreign spouses as to support the belief that they are not willing to do so. The Sakharovs know this, and must also suspect that the sacrifice on which they have embarked may prove fruitless: if they should die, Liza Alexeyeva will be even less well-placed than at present. The Sakharovs' courage is admirable and beyond dispute. Is it possible that on this occasion their isolation has led them to misjudge the future?

Andrei Sakharov's explanation lends some support to that unhappy guess. He complains that appeals for help with his immediate problem addressed to four members of the Soviet Academy have come to nothing, and that one of those asked — Academician Ya. Z'eldovich — had flatly refused to help on the grounds of the "shakiness of his own position". Sakharov goes on to accuse Z'eldovich of abandoning responsibility. It is, however, well-known in the West that Z'eldovich, a distinguished theoretical physicist turned cosmologist, is among that large company of Soviet scientists unable to accept invitations to conferences abroad. Sakharov's own protest against illiberality has hitherto been entirely admirable. In the loneliness of his exile, it is natural that he should be looking to others for help. What they do, and how they do it, is nevertheless for them to decide. That the Sakharovs themselves have fallen back on the hunger strike is especially distressing, not merely because of the risks involved but because the hunger strike is essentially an irrational form of protest. Governments may yield on particular points, but are unlikely to recast their policies as a result. More often, they dig in their heels, declining to give in to emotional blackmail.

#### Academic cat and mouse

Can Sir Keith Joseph, the least successful minister in the British Government, be trusted with the universities?

The proposition that higher education is too important to be left to educationists would be widely accepted. But can the future of British higher education safely be entrusted to Sir Keith

Joseph, the present Secretary of State for Education and Science? In a debate last week in the House of Commons, Sir Keith uttered this perplexing statement:

Those who maintain that it would be educationally less harmful but still productive of the same savings to go slower have not made out their case. I concede that logically such a case could be made, but I do not believe that it has been made.

If one is made I shall consider it.

If words, even as interpreted by *Hansard* shorthand writers, mean anything, he was saying that British universities have not yet found the forms of words with which to defend themselves against the folly of his government's decision that the university budget should be reduced by 15 per cent in three years At the same time, however, Sir Keith implied that if only academics were as smart as he is, they would get their act together and persuade him, as he secretly knows they could, that their case for a less draconian contraction makes economic as well as academic sense. And secure as he is in the kmowledge that no British academic will pass that stringent test, he will let the system founder.

Sir Keith has a curious reputation, more that of an intellectual than of a politician. His spell as Secretary of State for Industry is memorable chiefly for his advocacy of the importance of market forces and for his contradictory willingness to make out a cheque for whichever nationalized industry was then in trouble. Last week, he rightly challenged his critics to explain how an openended commitment by British governments to meet the cost of educating all qualified entrants could be reconciled with the limited capacity of taxpayers to meet the cost. The answer (which follows) is not arithmetical.

Sir Keith was right last week implicitly to say that no British government could permanently agree that all "qualified" students should be educated free, in the disciplines of their choice, at the taxpayers' expense. He should also have done the decent thing and said that Robbins, as a principle, is dead. What bothers the government about the open-endedness of its inherited commitment, however, is not so much the cost of operating the universities as that of paying maintenance grants to students. Sir Keith's officials are already negotiating with the National Union of Students on the students' demand that their maintenance grants should be increased by nearly 18 per cent. The officials will have at least one hand tied behind their backs by the legislation that compels each local authority to pay maintenance grants to students whenever they are awarded places at institutions of higher education. The profligacy of this legislation is, outside the United Kingdom, beyond belief. Not merely does it constitute Sir Keith's chief problem but it is the albatross hung around the neck of the university system. Replacing the present system of mandatory student grants, limitless in cost, with a system of scholarships awarded to deserving people would help not merely to solve the universities' problems but would get Sir Keith Joseph off the hook on which he has quickly (but characteristically) impaled himself. Unhappily, neither the universities nor the minister supposedly responsible for their welfare have the stomach for such a fight.

#### Monument for a giant

Sir Hans Krebs died this weekend in Oxford.

It is quite true that in the 1930s, *Nature* declined to publish Sir Hans Krebs's article on what most people have since called the Krebs cycle. The explanation given was that the article should be placed in a more specialized journal. Krebs himself cherished the rejection slip but modestly and confusingly always referred to the biochemical cycle he first described by its original name, the "citric acid" cycle (see *Nature* 291, 381; 1981).

Krebs, a refugee from Nazi Germany, carried with him Warburg's way of regarding the biochemical problems of metabolism and, perhaps more important, Warburg's techniques. But only Krebs's flair can account for his unmasking of the intricacies of the most rudimentary of the metabolic processes in animal tissues — the oxidation of sugars to form ATP — with the techniques of half a century ago. Inevitably, that single piece of work will be his chief monument. Another is in danger of being overlooked. Krebs, naturally a magnet for students, modestly bent his energies to teach them all he knew. At one stage, more than a dozen British chairs of biochemistry were occupied by his students. He was a giant eager that his shoulders should be used by younger people.

## MIT agrees to accept Whitehead grant

## Faculty votes yes, but some strings remain

Washington

Despite strong objections from several members of its science departments, the full faculty of Massachusetts Institute of Technology (MIT) voted by an eight-to-one margin last week to approve MIT's acceptance of an offer from multi-millionaire Edwin (Jack) Whitehead to set up an independent biomedical research centre associated with the institute.

The faculty's approval gives a green light to the MIT Corporation and the institute's president, Dr Paul E. Gray, to accept Mr Whitehead's offer of an initial \$20 million for the capital costs involved in building the research centre, and an eventual endowment of \$100 million to cover operating costs. The centre's main goal will be to pursue research into the applications of molecular genetics to developmental biology.

The money will allow the centre, which will be headed by Nobel laureate and MIT biology professor David Baltimore, to recruit at least 20 full-time professors. All will be members of MIT's biology department, since although funding for the centre will be controlled by members of Mr Whitehead's immediate family and other trustees nominated by him, the centre will for academic purposes be treated as an integral part of MIT.

When details of Mr Whitehead's original offer became known early in the summer, several faculty members complained that research staff at the centre would be subject to a "dual allegiance" that could lead to tensions between them and other MIT academics (Nature 1 October, p.329). Concern was also expressed at the original proposal made by Mr Whitehead - cofounder and president of the laboratory instrument company Technicon, which was bought by Revlon in August 1980 in a deal that involved the transfer of \$300 million in Revlon stock to him - that the research centre should own all the patents originating from its work and benefit directly from their licensing.

In the intervening period, the terms of the proposed arrangement have been modified to give MIT more direct control of the centre. Thus all new faculty members appointed to the centre will be required to adhere to existing MIT rules on salaries and benefits, and fulfil the conventional teaching and committee responsibilities of other MIT academics.

Mr Whitehead has insisted, however, that the funds for the centre, to be known

as the Whitehead Institute for Biomedical Research, remain under the control of its finance committee and that his three children should remain a majority on the committee. The conventional arrangement is for a benefactor to provide funds directly to a university, but he says that if he had wanted to give the money to MIT and let the institute decide how to spend it, he would have done so.

Not all the critics have been satisfied with the concessions that Mr Whitehead has agreed to. In a letter circulated before last week's meeting, 33 faculty members expressed their continuing "deep concern" about the implications of the proposed arrangements. The letter, drawn up by physics professor Anthony French and biology professor John Buchana complained that the centre's staff would be selected primarily for their potential contribution to its research activities rather than in order to meet MIT's educational needs; that the creation of the centre would lead to an imbalance in the biology department, since it would provide onethird of the full professors; and that there would be a lack of symmetry between the voting power of the centre's scientists over the work of the rest of the biology department and vice versa.

MIT officials, however, are keen to accept Mr Whitehead's offer, which they see as helping to keep MIT in the forefront of biological research and its potential

commercial application. In a letter circulated to all faculty members before last week's meeting, Dr Gray and MIT provost Francis Low said they shared the general concern about the potential problems that could arise as a result of the dual loyalty of faculty members. But they added: "Although this risk cannot be eliminated, in our view the worries are based on worst-case scenarios that are not likely to materialize".

After a sometimes stormy debate, in which Dr Gray said he did not know the detailed reasons why a similar offer from Mr Whitehead had been turned down by faculty members of Duke University in North Carolina in 1974, a motion to support the creation of the research centre was approved on a straw vote by a majority estimated as eight-to-one. At the same time, the motion said that members of the faculty "acknowledge the existence of legitimate, deep concern over the risks inherent in the venture, and hope that efforts to minimize these risks will continue".

Mr Whitehead's offer will now be formally considered by the members of the corporation, the controlling body of MIT, when they meet on 4 December, and is expected to be accepted. Dr Baltimore expects the new institute to get under way as soon as the affiliation had been formally approved by the corporation.

.. David Dickson

#### Mitterrand embraces information policy

M. François Mitterrand, President of France, is wasting no time responding to the "information shock" — the complex of issues surrounding microelectronics and unemployment.

In June, Mitterrand asked the publisher Jean-Jacques Servan-Schreiber (who had written a book on the subject) to gather a few experts to study the question. Servan-Schreiber's response came last week in a report which proposed the setting up of a world centre in Paris. This would gather together international experts in informatics, and have a budget of around £10 million a year (£4 million of which would pay the 60 staff). Within the week, Mitterrand had agreed and ordered that the details should be worked out within a fortnight. So the World Centre on Informatics should be in action in 1982.

What it will do, however, is not clear. Servan-Schreiber's vision is of a transformation of the world mediated by the development of the personal computer (something cheaper and more accessible than the present office and household machines). Such computers could make work more varied and creative, and provide everyone—including the Third World—with almost unlimited access to information. Development is a matter of

education, he says, and the personal computer can facilitate it. The world centre, therefore, should observe and assist this transformation.

Mitterrand, however, is aware that in industry the application of microelectronics might cause unemployment, and that the computer can interfere with liberty and privacy. At the same time, he considers that the economic development of France, and of other Western nations may depend on the rapid implementation of microelectronics and informatics. Elected to conquer unemployment, and determined to increase his country's economic strength, he needs an answer to this dilemma and hopes that the world centre, as a kind of full-time standing committee of academics, will provide it.

Although the precise form of the centre has yet to be determined, the staff is certain to be international. So far, ten experts have expressed interest in joining — seven from America, two from Scandinavia and one from China

If the centre develops as Mitterrand wishes, it will:

- Monitor the applications and effects of microelectronics worldwide.
- Forecast the possible role of France in these developments.

0028-0836/81/480297-02\$01.00

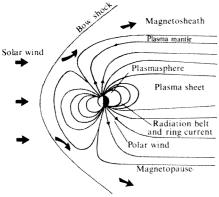

- Study how to educate users and potential users of microelectronics, particularly in relation to maintaining employment.
- Help develop new programs and languages appropriate to a personal computer (Servan-Schreiber version).
- Propose the means of transferring the technology to the Third World.

Robert Walgate

#### Magnetospheric experiment

#### UK joins in

The Science and Engineering Research Council has decided to fund participation by the United Kingdom, to the tune of £2 million, in the Active Magnetospheric Particle Tracer Explorers project (AMPTE). The council's Rutherford Appleton Laboratory, in partnership with the Mullard Space Science Laboratory of University College London and other university groups, will be developing the satellite as a separate component of the Ion Release Module satellite being developed by the Max Planck Institutes of

Astrophysics and Aeronomy in West Germany. The two satellites, together with the Charge Composition Explorer satellite being developed in the United States, will all be launched in mid-1984 on a Thor Delta rocket, hastily acquired following space shuttle delays.

The magnetosphere is the region where the magnetic field of the Earth interacts with the charged particles and magnetic fields of the solar wind, the continuous flow of plasma from the Sun. The aims of the experiment are to release lithium and barium ions into the Earth's magnetosphere and, by monitoring their subsequent behaviour, to investigate several fundamental aspects of the magnetosphere as well as to simulate conditions near other planets. The Ion Release Module will be placed in a highly eccentric orbit, so that ions may be released both inside and outside the magnetosphere.

One of the problems to be tackled by the Charge Composition Explorer is to determine whether or not the magnetosphere is "open" — that is, whether the Earth's magnetic field lines can connect with those of the interplanetary medium so that solar plasma can enter the Earth's field

from downwind. To this end, ions will be released just upstream of the bow-shock. The Charge Composition Explorer, in an equatorial orbit, will detect those ions only if the magnetosphere is "open".

The UK satellite will be placed in an orbit with that of the release module, maintaining a separation of 100 km or so. The particle and field detectors on board will monitor the behaviour of the ejected ions immediately after release. Lithium ions, being light, should pick up a large component of the velocity of the solar wind unless disturbed by plasma instabilities.

The release of the barium ions should produce rather more spectacular results. Because they are more massive than most components of the solar wind, the surrounding plasma will be impeded and a glowing comet-like structure will be produced. If the barium ions are released within the high-velocity plasma of the magnetosheath near dawn or dusk, the cloud will be visible from the ground, and will simulate conditions to be found in comets and in the magnetosphere of Venus. When released "downwind" in the magnetotail, where plasma flows more slowly, conditions will be more similar to those near Io and Titan within the magnetospheres of their respective planets Jupiter and Saturn. **Philip Campbell** 

#### NASA budget

#### Small is necessary

Washington

As the National Aeronautics and Space Administration (NASA) locks horns with the Reagan Administration over just how large a budget cut it must face next year, US space scientists are trying to devise a strategy for exploring the Solar System within the tight budget constraints likely to dominate for the next few years.

For the fiscal year beginning 1 October 1982, the Office of Management and Budget (OMB) has told NASA to prepare for cuts of about \$1,000 million in a budget previously projected at about \$7,000 million. Agency officials are strongly resisting this request, arguing that such a cut would severely damage all NASA's programmes; they have already gone over OMB's head to the White House in an attempt to get the proposed cuts reduced before the budget is formally submitted to Congress in January.

However, the prospects for NASA in general — and space science in particular — are likely to be bleak for the next few years. In this context, the agency has set up a Solar System Exploration Committee to take a close look at the type of projects it should be planning for the future. "If something disastrous were to occur to NASA's budget next year, it would be even more important to plan how we should recover", Dr Noel Hinners, the committee's chairman and director of the National Air and Space Museum in

Washington said last week.

The main aim of the committee is to increase the efficiency of planetary and other Solar System missions while reducing the costs, in particular by breaking down the scientific goals of the missions into "smaller bites" than those represented by, for example, Voyager.

One way of achieving this goal would be to build directly on the experience of previous missions. For example, the Ames Research Laboratory is looking at ways of developing Pioneer-type orbiters to some of the inner planets, using derivatives of terrestrial orbiters to study the geological characteristics of the Moon or Mars.

Pioneer-type spacecraft would only be able to achieve relatively limited scientific objectives, and would produce a relatively low data rate. But a mission could be launched for between \$100 and \$150 million, the same order of magnitude as the Explorer satellites currently being successfully used by NASA.

As well as looking at ways of using smaller spacecraft, the committee is investigating how to save money by increasing operations efficiency, for example by reducing the length of trips, compressing the scientific data to be transmitted back to Earth or the sharing of individual pieces of equipment between different research groups.

Four subcommittees will meet next month at the Jet Propulsion Laboratory to work out the type of programme that could be developed on the basis of such components. The subcommittees expect to report to NASA with specific mission proposals by next summer.

Dr Hinners said last week that he had discussed this new approach in some detail with officials at OMB, who expressed general approval but raised two possible objections. First that a list of the various missions which could be included in an overall envelope of between \$300 and \$400 million a year — only slightly above the current level — looked like an ambitious shopping list; and second, that breaking down planetary missions into smaller projects might lack the public appeal of Apollo or Voyager.

To the first objection, NASA replies that it is the size of the effort and the balance between costs and return that should be measured rather than the number of space vehicles flown. The second objection raises a broader question faced by NASA: can the apparently-increasing enthusiasm among the public for space exploration, particularly in the light of the excitement generated by photographs sent back by the Voyager spacecraft, be interpreted as a mandate to increase spending on space science?

Those who do believe that the public will be eager to support ambitious plans for space exploration are still pushing hard for what they consider should be the next major mission, a manned sample-return space vehicle to Mars. NASA administrator James Beggs told the advisory board last week that he shared the enthusiasm for such a project, although arguing that it should be planned in conjunction with what is likely to be NASA's next major project, a permanent orbiting space station which could be used as a base for manned planetary missions.

Members of the advisory board wondered whether there might be a danger that if NASA did embark on such a project it might further squeeze the space science budget, as the Apollo Moon landings and the space shuttle appeared to have done, but Dr Beggs tried to calm such fears. Admitting that the near-term looked relatively bleak, with no new planetary starts likely to be approved for 1983 or 1984, he replied that in the past the space science budget had done best precisely at those times when NASA had been able to generate political support for its major undertakings. **David Dickson** 

Diablo Canyon reactor

#### Licence revoked

Washington

The US nuclear industry has come in for an unexpected roasting from the new chairman of the Nuclear Regulatory Commission (NRC), Dr Nunzio Palladino. His criticism of its quality control was made before a congressional committee on the same day that the NRC voted to revoke a licence issued only two months ago to permit start-up tests at the Diablo Canyon nuclear reactor in California, on the basis of a series of engineering mistakes made when the plant was strengthened to resist earthquakes in the mid-1970s.

Six weeks of frequently-violent demonstrations by anti-nuclear protesters in September and October failed to stop the plant's owners, Pacific Gas and Electric Company, from proceeding with plans to start to load the reactor with uranium. The protesters claim that the plant is inherently unsafe because it has been built less than three miles from the Hosgri Fault, a branch of the San Andreas Fault system.

As the demonstrations were coming to an end, however, an engineer with the company discovered that a blueprint had been misread when the plant's support structure was being strengthened to compensate for the possibility of earthquake damage, causing the loads on various components to be miscalculated. Further errors found later included the misapplication of stress level numbers along the Hosgri Fault and the use of incorrect data in calculating the ability of pipes to withstand an earthquake.

Besides causing considerable embarrassment to the Pacific Gas and Electric Company, this discovery led to immediate pressure on NRC from Congress. The Reagan Administration has promised to speed up the licensing of new plants; but this strategy requires that public confidence should be maintained that safety is not being sacrificed in the process.

Appearing before the House Interior subcommittee, Dr Palladino, former dean of engineering at Pennsylvania State University, said that "after reviewing both industry and NRC past performance in quality assurance, I readily acknowledge that neither have been as effective as they should have been in view of the relatively large number of construction-related deficiencies that have come to light".

An order approved by the five-man commission, which voted 4-1 to suspend the low-power operating licence and unanimously for an independent audit of the quality control safeguards used by Pacific Gas and Electric Company, said that the suspension was necessitated by the seriousness of the errors in the initial review of safety modifications.

Following NRC's decision, the Pacific Gas and Electric Company issued a statement saying that it was "disappointed", since "nothing has been discovered to date that would indicate that the plant is not safe". The company claims that the plant had many redundant safety systems compensate for any threat from the Hosgri Fault.

David Dickson

#### More bickering about solar satellites

Washington

The National Aeronautics and Space Administration (NASA) seems unlikely to grant the request from the European Space Agency (ESA) to bring forward the launch of the International Solar Polar Mission, now due in 1986.

ESA had made this request following NASA's decision to stop work on the vehicle which it was to have provided for a dual-spacecraft mission, with the original intention that the two would pass simultaneously in opposing orbits over the poles of the Sun. European scientists had hoped that NASA, which will still launch the ESA space vehicle from the space shuttle, would be able to arrange an earlier flight to help compensate for the disruption and the loss of experiments which the cancellation has caused.

Last week, however, NASA officials said that the growing concern over whether the shuttle will be able to maintain an already overcrowded launch schedule means that a 1984 launch is virtually out of the question.

There is a slight possibility of a launch in 1985. However, since there is only a relatively short launch window in that year, and since the same window is required by the Galileo probe and orbiter scheduled to start its journey to Jupiter at the same time, the chances of arranging both launches within the same period seem slim.

ESA officials are still angry at the way in which NASA cancelled its proposed spacecraft; a resolution adopted by ESA's space programme committee last month suggested that ways should be explored of seeking some type of compensation from the US agency and ESA's secretary general Dr Quistgaard suggested the early launch date as one form of recompense.

US officials admit that it is the first

time NASA has had to go back on a previous agreement, but claim that the "memorandum of understanding" signed between the two organizations makes it clear that the solar mission agreement was subject to the availability of funding, and that NASA could not legally commit itself to more than one year's advance funding.

In addition, Dr Hans Mark, deputy administrator of NASA, told a recent meeting at the National Academy of Sciences that although the decision to cancel NASA's involvement in the solar mission was regrettable, there had been several occasions in the past when European governments had broken commitments, for example some of those made through the North Atlantic Treaty Organization.

On the first point, ESA claims that the memorandum of understanding had been agreed on the basis that normal funding procedures would be pursued by both sides — and that NASA is at fault not for having failed to provide the funding promised, but for having decided unilaterally to omit the project from its request to the Office of Management and Budget for the 1983 budget. On the point that some European organizations have broken commitments in the past, ESA argues that it is not fair to penalize ESA for failures of individual European states.

Meanwhile NASA scientists are discussing the possibility of launching an Explorer satellite into an ecliptic orbit around the Sun to coincide with the European spacecraft's encounter. This satellite, which would be launched in 1985, would provide baseline measurements of the solar wind — and that might go some way to making up for the deficiencies resulting from the decision not to send a full US spacecraft.

#### Uranium enrichment

#### **US-India** stand-off

New Delhi

India is trying to become self-sufficient in the production of fuel for its nuclear power plants following its bitter experience with the United States over the supply of low enriched uranium for the Tarapur plant in Maharashtra state.

The latest round of discussions between Indian and US officials has failed to break the impasse over the clearance of at least pending applications with the United

States for the supply of enriched uranium. The United States maintains that India should sign the Nuclear Non-Proliferation Treaty and open all its nuclear installations — indigenous as well as foreign-aided — for international inspection as required by the US Nuclear Non-Proliferation Act of 1978. The supposed fear is that a uranium reprocessing facility in India might be used to extract plutonium for atomic weapons.

India rejects this contention, however, arguing that the 1978 US legislation should not be applied retrospectively and unilaterally to a bilateral agreement entered into in 1963. India has said time and time again that its nuclear technology would be used for peaceful purposes only. India holds the Nuclear Non-Proliferation Treaty to be discriminatory, saying it includes only civilian establishments and specifically excludes military establishments of the nuclear weapon states which prescribe non-proliferation for others and not for themselves.

The issue is now a matter of principle — especially as India is now almost self-reliant for nuclear fuel production.

Indian nuclear scientists have developed mixed oxide fuel of uranium and plutonium which can work as alternative fuel in place of the enriched uranium supplied by the United States for the Tarapur plant. The only other operational nuclear power plant at Kota in Rajasthan utilizes indigenous natural uranium. The nuclear plants being built at Narora and Kalpakkam will also be pressurized heavy water reactors using indigenous uranium.

Sunil Saraf

#### US nuclear technology

#### Exports raise fears

Washington

Fears are mounting in Washington that the Administration's efforts to increase nuclear technology exports could be encouraging the proliferation of nuclear weapons. Last Thursday, members of Congress questioned the Administration closely about its agreement with Australia which, for the first time, would mean the United States sharing its knowledge of centrifuge technology for enriching uranium.

The criticism came only a few days after a new storm had broken over the ability of the International Atomic Energy Agency (IAEA) in Vienna to provide satisfactory safeguards against the diversion of nuclear materials from civilian to military use.

The decision to share enrichment technology with Australia is part of an effort to encourage US companies to participate in a joint venture with the Australian government to construct enrichment facilities for its nuclear industry. It was contained in a memorandum signed on 12 November by President Reagan which also instructed the Department of Energy to look at ways of

#### British academics at the barricades

Genteel academic militancy reached boiling point last week, with a mass lobby of the British Parliament by some 10,000 university teachers protesting not merely at the British government's decision that the university budget should be cut but at the uncertainty that remains about the arrangements that may (or may not) be made to deal with redundancies among academics. Some of the participants (see picture) wore fancy dress.

The lobby (on Wednesday, 18 November) coincided with a debate in the House of Commons on the planned reduction of the public subvention for universities, called by the Labour

opposition. One government speaker complained that it would have been more convenient if the debate had been arranged for the following day, so that those inclined to do so would have had a chance to listen to what the lobbyists were saying.

Both occasions followed by a lunch-time break the first appearance of Sir Keith Joseph, the new (since last month) Secretary of State for Education and Science, before the Select Committee on Education, at which he and his retinue of civil servants were unable to put into words a definition of the "Robbins principle", the doctrine that qualified candidates for university entry should be catered for. At the beginning of last week, the UK Committee of Vice-Chancellors also (unusually) made public its own account of an unsatisfactory meeting with the minister and a waspish letter it had written to him afterwards.

The debate in the House of Commons has confused and not clarified the immediate financial prospects of British universities. Sir Keith Joseph and his minister with special responsibility for higher education, Mr William Waldegrave, declined to answer the apparently simple question whether the government would pay the cost to universities of breaking contracts with tenured academics. Each of them said, however, that the British government would be prepared to "listen to" arguments that it would save money by extending the period over which the universities were now required to contract.

The Committee of Vice-Chancellors is now drafting such a document.

transferring the federal uranium enrichment programme into private hands.

During a hearing of the Senate Foreign Relations Committee's subcommittee on energy and nuclear non-proliferation, several members questioned Administration officials closely on this decision. Centrifuge technology has previously been subject to strong government restrictions, on the grounds that it could provide a relatively inexpensive way of producing weaponsgrade nuclear fuel.

However, the Administration continues to insist that, although a hard line will be taken with any country that diverts civilian technology to military use, in general IAEA provides the best way of minimizing the risks of proliferation through its safeguards and regular inspections.

This argument suffered a setback earlier this year when an ex-IAEA inspector, Mr Roger Richter, told the same Senate committee that IAEA had failed to detect efforts by the Iraqi government to work clandestinely on nuclear weapons, and that present IAEA safeguards were "totally incapable of detecting the production of plutonium in large-size material test reactors".

At the time, IAEA officials fiercely contested Mr Richter's conclusions, claiming that he had not been aware of all the relevant facts. However, it now looks as if they will have to go through the same process in defending themselves against criticisms made by another ex-inspector, Mr Emanuel R. Morgan, in a report commissioned for the Nuclear Regulatory Commission by commissioner Mr Victor Gilinsky.

The report — not officially released but leaked to the *New York Times* — echoes Mr Richter's conclusion that IAEA is incapable of detecting the diversion of a significant quantity of nuclear fuel "in any state with a moderate to large nuclear energy establishment".

This memorandum, likely to be discussed shortly in a congressional hearing, is the first critical assessment of IAEA's safeguards to have been prepared for a federal agency. The State Department issued a statement saying that although it accepted that the safeguards system was not perfect, there was "simply no alternative to an international safeguards regime".

#### Product development

#### British battle on

Brussels

The British government is fighting hard to exclude development risks from the EEC's draft directive on product liability now being debated in Coreper — the Committee of Permanent Representatives to the European Community. This has caused great consternation among the European consumer lobby group, Beuc. The consumer group fears that the exclusion of development risks would undermine the whole system of direct liability, by reversing the burden of proof and placing it on the consumer.

The alternative to development risks, the state-of-the-art defence, means that if the manufacturer can prove that he took all reasonable care in the light of the state of scientific and technical development to ensure that his product was safe, he avoids paying compensation. But who then compensates the consumer for his loss if a product, such as thalidomide, turns out to be dangerous? In the United Kingdom the Pearson Royal Commission and the Law Society, concluded that the manufacturer should bear direct liability for development risks. The Council of Europe has come to the same conclusion and France, Belgium and Luxembourg have signed a convention to that effect.

Belgium takes over the presidency of the Council of Ministers from Britain next year and the United Kingdom is anxious to have this part of the directive dealt with by then. The British argue, following pressure from the pharmaceutical industry, that development risks inhibit innovation and competitivity. In the last debate on this subject in the House of Commons, Sally Oppenheimer, the Minister for Consumer Affairs, argued that the EEC proposals would involve a major change for British manufacturers.

The experience in other EEC countries shows that the change is not as painful as alleged. For instance, the German law on pharmaceutical products provides for direct liability and manufacturers cover themselves by taking out an insurance amounting to 2 per cent of turnover.

The British are, however, confident that a compromise can be reached. This could involve excluding development risks or limiting them to pharmaceutical products.

Jasper Becker

US solar energy

#### Golden housing

Washington

Denying charges that the Reagan Administration is ideologically biased against solar energy in favour of nuclear, US Energy Secretary Mr James Edwards last week announced the go-ahead for the Solar Energy Research Institute (SERI) in Golden, Colorado, to start building a permanent research and test facility.

The Administration's decision is its first bit of good news for supporters of solar energy, whose budget within the Department of Energy has dropped from the \$707 million proposed by President Carter to less than half that in the current year.

Much of this reduction in funds had been felt at SERI. This institute, which is run for the Department of Energy by the Midwest Research Institute, has already had its budget cut from \$120 million to \$50 million, and staff reduced from \$60 to 650.

Since its creation in 1977, SERI has occupied temporary premises in the town of Golden, just outside Denver, Colorado. But it has also been planning a combined laboratory and showcase, to be located on a nearby mesa on land donated by the state.

Initial proposals for a solar research and demonstration centre costing \$124 million were reduced by the Carter Administration, which then requested \$24 million in the 1981 budget for the first stage of construction. One of the first acts of the Reagan Administration was to withhold all construction money on the grounds that it was re-evaluating its whole approach towards funding solar energy research.

At one point, it was rumoured that the Office of Management and Budget was contemplating eliminating all funding for such research from the Department of Energy's budget. Publicly, however, the Administration has stated that although it is eliminating demonstration projects which it feels ought to be supported by the private sector — if at all — it accepts the need for federal support of long-range, high risk research.

The permission from the Department of Energy for construction of SERI's laboratory is being used by the Administration to symbolize a commitment to solar power. But Mr Edwards said that the \$9.5 million which he was making available for the initial construction phase — money from appropriations previously authorized by Congress — did not necessarily mean extra funds for energy research.

But the decision to fund SERI's laboratory does not necessarily mean that federal support for solar energy research will be generous. The rumour in Washington is that the Department of Energy's budget request for 1983 contains a meagre \$93 million for all solar energy work, a contraction to the level of the early 1970s.

#### Californian Medflies

#### **Innocent victims**

Palo Alto, California

If aerial spraying with the insecticide malathion is used to counter the threat of Mediterranean fruit fly in California this winter, an unexpected casualty might be one of the oldest continuously studied insect populations in the world.

Jasper Ridge is a 1,200-acre natural wilderness to the west of the Stanford University campus in California, between suburban San Jose and the city of San Francisco. More than 120 dissertations and papers have been written about the area since 1897 when studies began in earnest. So far, Jasper Ridge has been a virtually unsprayed island, surrounded by a 600-foot buffer zone. But in July spraying began in areas next to the reserve.

Most immediately at risk, of course, are the insects themselves, notably the checkerspot butterfly *Euphydryas editha*, which has been the subject of a continuous population study since 1960, under Professor Paul Ehrlich.

Paul Ehrlich may search in vain next year

Although Jasper Ridge has not been sprayed directly, minute droplets of malathion bait (20-40 µm) have been found on plant leaves within the reserve. and these droplets must have drifted into the area from nearby spraying operations. During the summer, the drifting droplets did not appear to affect the checkerspot butterflies, which lay dormant under ground. But in the rainy season the checkerspots emerge to feed, and any direct spraying during the winter would almost certainly mean their complete disappearence from Jasper Ridge. Aerial spraying has been curtailed for the winter months, but will be stepped up again next spring (see Nature 12 November, p. 103).

Direct spraying would almost certainly be carried out, however, if two adult Medflies, or a pupa, were found within the Jasper Ridge reserve. The ecological balance of the reserve would then be irretrievably disturbed by an uncontrollable variable. Donald Kennedy, a biologist and Stanford University president, compares the possible loss of Jasper Ridge with the loss of an irreplaceable library. Charlotte K. Bevers

#### CORRESPONDENCE

#### Alchemy in cancer

Sir — Your editorial (*Nature* 5 November, p.1) describing the attitude of the sponsors of cancer research in the United States towards those who perform the research was most timely. The relationship between sponsor and sponsored in research generally is presumably similar except that in cancer research the goal is more visible and unease at the failure to achieve it more acute.

Without wishing to push the analogy too far, there is an apparent similarity in the relationship between workers in cancer research and their sponsors on the one hand, and on the other, the alchemists pursuing the philosopher's stone at the behest of their princely masters. It is a sobering thought that many alchemists lost their heads for failing in their sphere of endeavour. Fortunately, nowadays, it is only our jobs that are at risk.

#### Creationism

SIR — Our letter "American Creation" (Nature 2 July, p.95) appears to have resulted in two misunderstandings. The first, implied by the misleading title, is that it was primarily a critique of American Creationism. It clearly was not. The second, that we argue for a "God of gaps" by resorting to the supernatural to fill the gaps in current scientific knowledge, requires more serious consideration, since we agree with Sidney Fox (Nature 6 August, p.490) that such a view is a "copout" scientifically and theologically.

In common with most creationists, we acknowledge that faith is based on revelation and on personal knowledge of the Creator The only empirical evidence to support the assertion that all nature, however adequately or inadequately explained, is God's handiwork, is the fact that all things exist, and show evidence of design and purpose which reflect the revealed nature of the Creator. Given belief in such a Creator we expect to find evidence consistent with his revelation of himself. No doubt an atheist will likewise expect to find evidence consistent with his philosophical position and is likely to leave discordant data to one side in the belief that future study will show it to be either erroneous or, given further data, assimilable to his present beliefs. In that sense it is indisputable that since scientific knowledge is incomplete. gaps exist in any account of the natural world.

Furthermore we would argue that the primary purpose of man's quest to understand origins is philosophical not scientific, and that in a society that will not tolerate a personal infinite God, the purpose of evolutionary theory is often the justification of atheism. In this context it is critical that scientific evidence be analysed within a completely objective framework, before presuppositions are imposed upon it.

Our position is that we believe that existing evidence does not disprove the existence of a Creator and further that the most probable explanation of his activity as Creator is one which does not accord with current evolutionary theory. In examining the factual evidence available in biology we consider that the correct objective approach to biological

systematics is to employ cladistics, a methodology which might usefully be applied also to protein and nucleic acid sequences. The interpretation of such an analysis is subjective, resting on philosophical presuppositions. So any evolutionary relationships that exist are properly deduced from cladistics.

So far as the origin of life is concerned we suggest that the most likely interpretation of scripture is that life did not evolve from a prebiotic soup. Thus we are not surprised that there are difficulties in proposing plausible chemical mechanisms to support the spontaneous generation position. For example, to take Fox's experimental model, we agree that while plausibility can be argued indefinitely, nonetheless the only basis on which the plausibility of such a model may be assessed, however subjectively, is by an examination of the experimental data. Although we do not think it appropriate here to enter into detailed technical comments, we find Fox's data (Biosystems 12, 55) singularly unconvincing.

#### Malaria debated

SIR — I have read the paper by Chapin and Wasserstrom (*Nature* 17 September, p.181) with interest. I am disappointed with the presentation and discussion of the important subject of malaria resurgence and its relationship to agricultural production.

The authors give a garbled account of the very concept of malaria eradication and especially of the causes of the relative failure of this great endeavour. They imply that the main obstacle to the early achievement of the planned goal was resistance of Anopheles to insecticides. This is not so, even though the latter phenomenon played a significant part in technical problems that the World Health Organization (WHO) was facing during the late 1960s. The most comprehensive analysis of the multiple causes of the disappointing progress of malaria eradication in some parts of the tropical world was presented by WHO in 19691. It pointed out that administrative, social, economic and financial factors were largely responsible for the resurgence of malaria at the end of that decade, especially in

There is nothing "ironical" in the fact that agriculture in India and elsewhere expanded in regions where malaria incidence decreased spectacularly. It is precisely because of the improved health conditions, due to the use of residual insecticides against *Anopheles* vectors, that efficient agriculture became possible not only by rich landlords but also by small farmers. The astounding graph showing the positive association between the use of DDT in India and the striking increase of malaria in 1969–77 cannot be accepted in support of the authors' thesis of a causal relationship between the two factors.

An epidemiological analysis of the resurgence of malaria in India, such as the one carried out by Akhtar and Learmonth<sup>2</sup>, showed that the increase in the incidence of malaria in India from 350,000 cases in 1969 to nearly 2 million in 1973 and then to 5 million

in 1975 was due to other conditions with an adverse affect on the standard of anti-malaria operations in India and in other countries of the subcontinent. The military conflict with Pakistan, the sharp fall in the flow of American aid and the temporary food shortages due to bad harvests took place during that period. There were delays in the allocation of foreign exchange for insecticides and drugs and there was some loss of urgency of the malaria control campaign because of its good results and the emphasis on family planning.

The successful 1965-69 phase of malaria eradication in India left uncompleted four large areas from which the consequent resurgence spread. These were the Rann of Kutch in western India, Madhya Pradesh hill forests. Orissa hill forest tracts and the forested areas of Assam. Akhtar and Learmonth<sup>2</sup> indicated that densely populated areas, with extensive irrigation and high agricultural production, have shown less malaria than other areas during the period 1970-75. On the other hand, in spite of the continuous use of DDT for agricultural needs, the amount of malaria in India decreased sharply between 1977 and 1980, thanks to better implementation of control programmes.

A series of valuable studies by Indian experts<sup>3,4</sup> and an Audit Report of the Agency for International Development<sup>5</sup> attach much less importance to the problem of insecticide resistance and could be quoted as an argument against the thesis so eagerly adopted by Chapin and Wasserstrom.

The adverse effects of excessive use of residual insecticides in agriculture have been known and stressed by WHO for well over a decade. It is quite untrue that WHO did not urge all countries in the developing world to decrease as much as possible (without endangering their food and health programmes) the use of residual insecticides and to introduce alternative methods of pest control. The emphasis on this policy was clearly stated in the 16th Report of the WHO Expert Committee on Malaria<sup>6</sup> and was repeated and emphasized in the 22nd Report of the WHO Expert Committee on Insecticides7 and in every other relevant WHO report.

The serious imputation that the Food and Agricultural Organization (FAO) policy is being influenced by large insecticide-producing companies will certainly be answered by those accused of irresponsibility or other more sinister intentions. The authors use with evident relish the impressive term "integrated control" although it is doubtful that they fully understand its practical implications. Integrated pest management means a combination of chemical, biological and environmental methods. The complexity of implementation of these methods is often difficult to fathom by non-specialists, who invoke the term with more heat than light and over-estimate its universal feasibility. Integrated control methods are certainly successful in some areas with important crops but they must be tailored to local conditions. Their use requires not only a constant assessment of the size of the pest population but also carries with it the uncertainty of

#### NEWS AND VIEWS

## MARS

From Philip Campbell

THE exploration of Mars by spacecraft began in July 1965, when Mariner 4 passed 12,000 km above its surface and provided the first direct evidence for the existence of craters, a weak magnetic field and a thin atmosphere. Mariners 6 and 7, approaching the planet to within 3,500 km in 1969, indicated that craters were a predominant land form but also revealed the existence of chaotic terrains of irregular ridges and troughs. Carbon dioxide was identified as an important atmospheric constituent, although geologically speaking the planet appeared to be similar to the Moon.

This impression was altered dramatically in 1971 with the arrival of Mariner 9 (the first spacecraft to orbit another planet) and the Soviet Union's Mars 2 and 3 spacecraft. Mars 3 contained a lander that was successfully placed on the martian surface; regrettably, its television camera failed after 20 seconds. Mariner 9 comprehensively mapped the surface and revealed (when dust storms had cleared) not only craters but channels, volcanoes and canyons, all of super-terrestrial proportions. It became obvious that Mars was a more dynamic

planet than had been thought.

Since that time, the planet has been visited by six Soviet and American spacecraft, including the most sophisticated and ambitious of all planetary probes — Vikings 1 and 2. The data provided by the latter orbiters and landers since their arrival in 1976 still occupy the minds of planetologists, as evidenced by the continuing series of regular international colloquia on Mars.

The third of these was held at the California Institute of Technology last August; the full proceedings will appear in the Journal of Geophysical Research next year. Several speakers were invited by Nature to present articles on topics of their choice, concentrating on particular aspects of Mars' solid body and its gaseous envelope, and reflecting to some extent the ground covered at the meeting. The six articles that follow, therefore, are not intended to represent a comprehensive survey of the planet. Nevertheless, it is hoped that they will provide a vivid impression of the radical advance in our understanding over the past few years, and even rekindle some of the excitement that prevailed when the Vikings touched down.

One topic that is barely mentioned here is martian biology. It should be remembered that the Viking landers are sitting on sites where biological activity was thought most likely to be found. But the door on this topic might be said to have closed at the previous colloquium, when it was concluded that the top 10 cm or so of soils at the two lander sites were bereft of organic compounds. A forlorn refrain running through the following articles is the need for further visits to the planet; when such a return materializes, seekers of life will probably want to drill deeper into the surface, where complex molecules may find existence more congenial.

The only future Mars mission known to be under active consideration is the European Space Agency's Mars orbiter, the Kepler mission. If Europe decides to proceed with it, Kepler should be launched towards the end of this decade. Meanwhile, the Viking 1 lander is reactivated at regular intervals to return pictures such as that on the left. But planetologists are trying to salvage what they can from future budgets (as reported in the News section). Will these articles mark the end of this period of unprecedented exploration?

Philip Campbell is a member of the editorial staff of Nature.

#### The geophysics of Mars: whence the Tharsis plateau?

from Sean C. Solomon

THE planet Mars, since the first global views of its surface were sent to Earth by Mariner 9, has been regarded as a key member of the terrestrial planetary family. Intermediate in size between the larger (the Earth and Venus) and the smaller (Mercury and the Moon) bodies, Mars also appears intermediate in the vigour and duration of its tectonic and volcanic activity. Roughly half of its surface is pock-marked with impact craters and basins that formed, by analogy with the Moon, over  $3.8 \times 10^9$ years ago. One third of the surface consists of younger volcanic plains, here and there capped by prominent volcanoes. Major concentrations of volcanoes occur in two broad provinces marked by high surface elevations, positive gravity anomalies and an extended history of surface faulting. The largest of these two provinces, the Tharsis plateau, provided a major focus for new ideas and widespread discussion at the colloquium.

As a backdrop to the discussion of Tharsis, it is well to remember the vast difference between the level of our knowledge of Mars and that of either the Earth or the Moon. We know the planetary mean density and, with less precision, the moments of inertia for Mars, yet we know little of the nature of the Martian mantle or the nature and size of any high-density core. Whether Mars has an internal magnetic field is debatable and is unlikely to be settled by existing data. We have gravity and topographical data of limited coverage and variable accuracy for Mars; we nonetheless do not know the nature and thickness of the martian crust. A relative chronology for major geological units has been derived from crater density measurements; the true ages of martian surface features are not known. The geometry and some relative age information have been obtained for the principal tectonic features, but we do not know the true ages of major tectonic events or the present level of tectonic activity. We are completely ignorant of martian heat flow and of the abundances and distribution of heat sources within the

We are therefore faced with the task of understanding the volcanic and tectonic history of Mars in general, and of Tharsis in particular, without the information on the seismic structure or present thermal regime of the interior that we rely on for similar studies of the Earth and Moon. As a further handicap, that history cannot yet be anchored to the radiometric age of a single martian rock sample. The principal

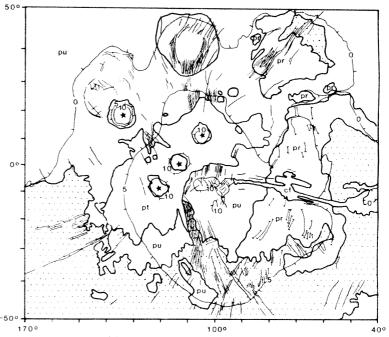

Sean C. Solomon is in the Department of Earth and Planetary Sciences, Massachusetts Institute of Technology.

tools at our disposal in this endeavour are images of the planetary surface, gravity anomalies inferred from the acceleration of orbiting spacecraft, and topographical measurements obtained from photogrammetry and Earth-based radar.

The Tharsis region of Mars (see the figure) is a broad plateau 4,000 km in diameter and standing as much as 10 km above the level of the surrounding terrain<sup>1</sup>. The plateau is covered by relatively young volcanic plains and includes a number of volcanic constructs large and small. There are numerous extensional fault systems and graben that generally predate the youngest volcanic plains and that display a

of most extensional fractures in and near the Tharsis area.

Recent calculations<sup>5,6</sup> of the stresses in the martian lithosphere have called the uplift model, as originally proposed, into serious question. Because the Tharsis region is so large relative to the planetary radius, full spherical calculations including both membrane and bending stresses are necessary to model the response of the martian lithosphere at Tharsis to either doming or loading. An uplift model for Tharsis leads to the prediction<sup>6</sup> of radial compressive features at distances from the plateau centre at which radial graben and extensional features are actually observed.

The Tharsis region of Mars<sup>1,4</sup>. Contours give topographical height in km above Mars datum. Ancient cratered terrain is indicated by light shading. Major volcanic constructs are indicated by heavier shading; the summits of the four largest volcanic shields, indicated by stars, exceed 25 km in elevation. The volcanic plains units include the ridged plains (pr), the younger Tharsis plains (pt) and the undivided plains (pu). Tectonic features include the extensional faults systems (lines), mare ridges (lines with ticks) and the Valles Marineris canyon system (cf).

crudely radial geometry with respect to the centre of the elevated terrain. There are also tectonic features analogous to lunar mare ridges, presumably the result of horizontal compressive stresses, that are more nearly circumferential to the Tharsis plateau.

The traditional explanation<sup>2-4</sup> for the origin and evolution of the Tharsis region is that broad updoming of the martian lithosphere caused by a thermal or chemical anomaly in the mantle led to fracturing, volcanic emplacement of thin plains units, and finally the formation of the youngest large shield volcanoes. Supporting evidence includes the broad topographical height of the Tharsis region, the large elevation of surface units thought to be relatively old from the density of craters and fractures, and the radial trends

As a result, two alternative models for the origin and evolution of Tharsis have recently been put forward. An 'isostatic' model, first proposed by R. J. Phillips and N. H. Sleep<sup>7</sup>, is based on the hypothesis that the topographical height of the Tharsis plateau, and an additional subsurface excess mass required by gravity data, are compensated isostatically by a low density region of the mantle extending several hundred kilometres deep. The low mantle densities may be partly thermal in origin; A. A. Finnerty and R. J. Phillips also described a mechanism whereby the low densities would result from the depletion of lower melting-point basaltic material in the mantle beneath Tharsis.

A contrasting 'flexural' model for Tharsis, proposed by Head and Solomon<sup>8</sup>, is based on an extrapolation to a larger

scale of the geological processes seen in a number of areas on Mars: volcanic loading of the lithosphere, faulting in regions of thin lithosphere or in response to the flexural stresses resulting from large loads, and a concentration of continued volcanic activity in regions of widespread extensional failure. According to this model, much of the topography of Tharsis is due to volcanic construction, and a portion of the topographical load is currently supported by the finite strength of the martian lithosphere.

How can these two contrasting models be distinguished with our existing information on martian structure and evolution? One useful exercise, conducted by J. B. Plescia and R. S. Saunders9 and independently by R. A. DeHon, is to estimate the thickness of the volcanic plains units on the Tharsis plateau from the rim heights of craters partially buried by the plains material. These studies yield estimates of 3-5 km for the maximum thickness of the Tharsis volcanic plains that postdate the heavy impact bombardment of Mars (which probably ended about 3.8 × 109 years ago). Left unanswered by such studies, however, is the question of whether the heavily cratered surface underlying the young volcanic plains in the Tharsis area may itself represent the accumulation of older volcanic units. Thus the total thickness of volcanic material in the Tharsis region is unknown.

The tectonic history of the Tharsis region - the formation of faults of particular types and geometries in particular locations at different stages in martian geological history — holds important clues to the mechanisms responsible for Tharsis. R. S. Saunders and J. B. Plescia described evidence for distinct stages in the development of Tharsisrelated graben and extensional faults; each stage was marked by a different centre of activity. T. R. Watters and T. A. Maxwell addressed the question of the relative ages of mare-type ridges and extensional features where the two types of fault system intersect. Although the evidence that one type of fault is consistently older than the other is equivocal at present, the issue is very important for our understanding of the evolution of Tharsis, since the two types of fault cannot be produced at a given location by a single stress field.

A promising line of research is to combine the information on the history of faulting with calculations of lithospheric stresses as constrained by topographical and gravity data. Calculations by R. J. Willemann and D. L. Turcotte and by R. J. Phillips and W. B. Banerdt have shown that models in which the Tharsis plateau acts as a load on the martian lithosphere predict stresses in broad agreement with observed tectonic features. Phillips and colleagues are finding evidence that older fault systems in the Tharsis area fit best with an 'isostatic' model, while younger fault systems fit better with a 'flexural'

model. The need to keep open the possibility that Tharsis tectonic activity may have also been influenced by globalscale processes was underlined by P. H. Schultz and A. B. Lutz-Garihan, who argued that layered deposits near the martian equator once marked the location of the planet's rotational axis; large-scale polar wander on Mars would have led to global stresses in the martian lithosphere sufficiently large to affect tectonic activity in Tharsis and elsewhere.

If there was a consensus at the colloquium on the nature and evolution of the Tharsis region, it was that none of the simple models for Tharsis topography and tectonics (uplift alone, purely isostatic support, or solely volcanic construction and lithospheric flexure) is likely to be completely adequate. Continued work towards refining and testing these alternatives is clearly warranted. Tasks of high priority for martian geophysical studies in the near future include further elucidation of the chonology of tectonic activity, continued reduction of Viking Orbiter gravity data, new measurements of martian topography with Earth-based radar, and continued development of quantitative stress models to test hypotheses for Tharsis against these new data. For the longer term, our understanding of martian geological evolution will be limited by the large gaps in our information on the planet's surface and interior. Those gaps can be filled only by returning to the planet with new spacecraft experiments.

#### Volcanism on Mars

from James W. Head III

Single volcanic eruptions, such as the awesome Mount St Helens event, and the frequent spectacular basaltic eruptions on Hawaii, serve to focus our attention on active volcanic processes. Instructive as these local events are, we should not lose sight of the basic reasons why the study of planetary volcanism is important.

If we were to make a list of fundamental things we wanted to know about a planet, two questions would appear high on the list. First, what is the planet made of, and second, how does the planet generate and get rid of its heat? Complete answers to these two fundamental questions require detailed and direct examination of the interior of a planet and a knowledge of how that interior has changed with time. Since it is extremely difficult to examine the interior of a planet directly, we are forced to rely on largely indirect means to answer these questions. The record of planetary volcanism on the surface of a planet is the most important indirect evidence we have.

For example, the record can tell us a lot about the composition and state of the interior. The mere presence of volcanic deposits implies partial melting in the interior and a state of stress in the lithosphere favourable to eruption. In addition, volcanic deposits supply compositional information directly in the form of samples, and indirectly through remote sensing and the interpretation of volcanic morphology. Information on thermal evolution can also be obtained -

James W. Head III is in the Department of Geological Sciences, Brown University, Providence.

might, for example, compare the volcanic record of the Moon, where 100 per cent of the surface volcanic deposits were emplaced in the first 50 per cent of history, with the Earth, where 70 per cent of the surface volcanic deposits were formed in the last 5 per cent of Solar System history. Clearly, the two bodies had different thermal histories. The individual deposits on a planet and their variation with time are thus important clues to a planet's thermal evolution. Volcanism can also be related to other processes - volcanism and tectonism are often closely interlinked, as in the dramatic Tharsis region of Mars (see review by Solomon), and the volatiles comprising planetary atmospheres must be tied in some fundamental way to planetary outgassing and the history of volcanism.

These general themes raise specific questions about volcanism on a single planet such as Mars. The first task at hand is the identification and characterization of volcanic deposits. The range of morphological features (for example, shields, cones, flows) must be established, and some quantitative measure of these morphologies and estimates of their relative abundances made. At the conference, R. Pike and G. Clow (US Geological Survey) reported quantitative measurements of martian volcanoes and comparisons with similar structures on Earth, concluding that there is good evidence for three separate classes of volcano on Mars and that most martian shields differ substantially from terrestrial shields. These data are of the utmost importance for the characterization and

Oblique view of the massive martian shield volcano Olympus Mons. Recent topographical data (S. Wu et al. 3rd int. Colloq. on Mars, 287-289), indicate that the peak rises some 26 km above Mars datum, and that the caldera complex is about 80 km in diameter. A scarp up to 8 km in height surrounds the 600 km wide shield.

understanding of eruption conditions. C.A. Wood (NASA Johnson Space Center) compared calderas on Mars and Earth and noted the relatively low abundance on Mars, attributing it to the lack of both plate tectonic subduction zones and associated abundant silicic volcanism on Mars. S. Wu and co-workers (USGS) presented a topographical map of the massive Olympus Mons shield volcano (see figure), and E. Morris (USGS) described much new photographic data on the structure of this shield, the nature of its basal scarp (rising 4-8 km above the surrounding plain), and on the distribution and characteristics of the thin, lowviscosity flank flows. M. Zeitner (University of Washington) presented evidence that some of the circular craters associated with graben on Mars may represent maar-type eruptions. A study of the distribution and properties of small cones on Mars (H. Frey and M. Jarosewich, NASA Goddard Space Flight Center) provided data to help distinguish between origins as cinder cones, pseudocraters and pingoes. Variations within and between regions suggest multiple origins for the martian examples. P. Spudis and R. Greeley (Arizona State University) des-

cribed the geology of Tyrrhena Patera, an ancient central vent volcano in the cratered terrain, and interpreted its structure as representing a style of martian pyroclastic volcanism that may have been more common, but not abundant, in early martian history. G. Schaber, K. Tanaka (USGS) and J. Harmon (National Astronomy and Ionosphere Center, Arecibo) reported topographical data from Earth-based radar observations and several new volcanotectonic collapse features and previously unmapped lava flows within Syrtis Major Planitia. The topographical data show a dramatic 5 km rise near the edge of Syrtis Major, rather than the gently sloping surface previously thought to represent the topography. The authors suggest that the elevation of the entire Syrtis Major feature, the previously reported absence of any basin rim mountains or rim ejecta, the rapid decrease in elevation into Isidis Planitia, and the absence of any strong gravity anomaly centered on Syrtis Major, all indicate that the early geological history of this feature does not include the formation of an impact basin as postulated earlier. The feature appears to consist instead of a vast volcanic sequence whose source fissures

(probably concentric to the Isidis Basin), and subsequent extrusive episodes are related to crustal fracturing or fracture rejuvenation following the Isidis impact event early in martian history.

Characterization also requires data on the composition and physical properties of these units. Here remote sensing plays an extremely important role. On the Moon, we have nine sample return sites, yet global characterization of volcanic deposits is still mainly derived from remote sensing data. On Mars we have no sample return sites so we must rely on remote sensing data even more. Remote sensing can provide data on the composition and physical properties of surface materials and can also be used to distinguish, characterize and map surface units. H. Kieffer (USGS) reported a series of global maps of Mars data that have been compiled to similar scales; they will be of great importance in global mapping of volcanic deposits. J. Zimbelman and R. Greeley (Arizona State University) studied the surface properties of the Ascraeus Mons shield using remote sensing data and showed that its surface is characterized by a uniform average particle size, arguing against the presence of localized ash deposits. T. McCord (University of Hawaii) and co-workers used Viking approach images to define global surface units and a range of other information -Viking orbital, Earth-based telescopic spectral and albedo data - to characterize these units. The maps emphasize the composition of surface units and differ from traditional geological maps in that they include condensates and eolian deposits as well as bedrock units. The approach holds great promise for distinguishing and characterizing volcanic units on Mars

Another promising area is the investigation of Earth samples with similar spectral properties to surface units on Mars. D. Evans (University of Washington), R. Singer (University of Hawaii) and co-workers showed that certain weathered basalt tephras and a basalt coating from Hawaiian rocks have similar spectral characteristics to surface units at Viking Lander 1 and to some global units. The final results for the chemical composition of martian fine-grained soil from the X-ray fluorescence spectrometers at the Viking landing sites [B. Clark (Martin Marietta) and A. Baird (Pomona College)] can be interpreted as representing a primary crustal rock type, a mafic flood basalt rich in pyroxene.

An understanding of the range of eruption conditions represented by the deposits and their significance in terms of magma types, volatiles and the state of stress in the lithosphere can be approached by looking for direct morphological analogy with features on Earth. This approach may help to establish the volcanic nature of major landforms, such as the shields, but may be quite misleading for understanding the eruption conditions

leading to specific features on Mars. We know, for example, that gravity and atmospheric density differ between Earth and Mars and can markedly influence eruption conditions and resulting landforms. It is important, therefore, to consider the process of ascent and eruption of magma on Mars from first principles and to develop from these theoretical analyses predictions of the types of volcanic landforms that might be produced in the martian lithospheric and atmospheric environment. L. Wilson (University of Lancaster) and J. Head (Brown University) presented theoretical analyses of the behaviour of both volatile-free magma and magma containing volatiles and the resulting deposits and landforms. A specific example interpreted as a relatively young pyroclastic air-fall deposit on the flanks of Hecates Tholus was described by P. Mouginis-Mark, (Brown University) and Wilson and Head. From deposit characteristics and models of explosive eruptions, possible eruption conditions for this unique deposit were outlined. Although ash deposits had been thought of as candidates for various units on Mars, this appears to be the first identification of a specific deposit from a source region.

Armed with data on the characteristics of deposits and the range of eruption conditions, it would be useful to know the distribution and volume of volcanic deposits in space and time. Greeley and Spudis (Rev. Geophys. Space Phys. 19; 13-41, 1981) have recently reviewed the field and it is obvious that we have a long way to go to identify and characterize deposits and to relate them to the impact crater chronology. Progress in this area was reported by P. Francis (Lunar and Planetary Institute, Houston) and C. Wood (NASA Johnson Space Center), who reviewed evidence that silicic pyroclastic volcanism on Mars is unlikely to be a major process.

J. Plescia and S. Saunders (Jet Propulsion Laboratory, Pasadena) and D. Scott and K. Tanaka (USGS) have recently compiled stratigraphies of the volcanic deposits in the Tharsis region of Mars. Although information is accumulating, our understanding of the significance of these data for the thermal evolution of Mars is hampered by a lack of returned samples and of a knowledge of absolute ages. L. Martin (Lowell Observatory) reviewed evidence for possible volcanic activity on Mars during the Viking mission. Despite the excellent geological maps of the USGS, Dave Scott (USGS) showed that many volcanoes and volcanotectonic structures in the western hemisphere of Mars could be mapped using newer Viking Orbiter images, particularly in the older parts of the martian crust.

Where do we stand in terms of achieving the basic objectives outlined above? On the basis of the conference results, it is obvious that much more work of the type reported at the conference is required to characterize the martian volcanic record. We need to integrate the full range of remote sensing data in order to complement surface morphology with information on composition and physical properties. Some of this information is available, but much remains to be collected from Earth-based observations and from spacecraft near, and on, Mars.

Some of the basic theory of magma ascent and eruption on Mars has been worked out but much work needs to be done to compare present deposits with the theoretical predictions. This will help to establish the full range of eruption conditions and the implications for magma composition and the role of volatiles from both deep and shallow sources. The dis-

tribution of volcanic units in space and time is becoming better known but is far from a level which can constrain thermal evolution. Continued comprehensive mapping is required. A major problem is the nature and level of volcanic activity in early martian history during the time of high impact flux. Even with such information in hand, an absolute chronology is required before the thermal evolution of Mars can be understood.

In summary, progress towards these goals can be made with existing data, but major strides in these areas of fundamental importance to the evolution of planets requires new data of a variety of types, data obtainable by returning to Mars with properly instrumented spacecraft.

#### Martian geology

from Michael H. Carr

In addition to volcanism a wide range of geological topics, including channel formation, subsurface migration of water, simulation of martian ejecta patterns and sedimentation at the poles, were discussed at the colloquium. Surficial deposits such as the regolith and the relatively mobile eolian cover received most attention, possibly because a wealth of new experimental and observational data now allows them to be treated in quantitative terms.

Several papers were concerned with weathering. It has been suggested that UV light has an important role in chemical breakdown of materials on the martian surface but new data (M.C. Booth and R.V. Morris, Johnson Space Center) show that under martian conditions, with modest partial pressures of H<sub>2</sub>O, oxidation of magnetite, dehydration of goethite and breakdown of silicates take place at rates independent of UV radiation. Other experiments (T.R. Blackburn) show that breakdown of sulphides to sulphate can also occur without irradiation but breakdown is more rapid in samples irradiated by UV. R.L. Huguenin (University of Massachusetts) expanded upon his frost weathering model in which dissociation of adsorbed water on mineral grains and migration of hydrogen ions to lattice defects allow recombination of the OH- radicals left on the surface to produce  $H_2O_2$  — possibly the active oxidant needed to explain the Viking biology results. The reactions he proposes are all exothermic and do not depend on UV radiation, suggesting the role of UV in martian weathering is less important than previously thought.

The precise nature of the weathering products remains uncertain. Attempts to

Michael H. Carr is in the US Geological Survey, Menlo Park, California. match telescopic reflection spectra of Mars bright regions with various terrestrial materials have shown the Mars spectra to be inconsistent with ferric oxides or ironbearing clays. The best fit is with palagonite, a largely amorphous reaction product of basaltic lava with water which had been previously suggested by several workers, including the Viking Inorganic Analysis Team, to be a possible Mars surface material. However, A. Bonin reported work at the Hebrew University, Israel, on simulation of the results of the Viking biology experiment. He showed that Fe-rich clays can catalyse decarboxylation and/or oxidation of organic acids and was able to reproduce accurately the Viking labelled release results. Fe-rich clays were also used successfuly to simulate the gas exchange and pyrolitic release experiments.

The distribution and physical nature of the surface debris attracted attention from a number of workers. A map of the global distribution of different colour units identified on a planet-wide plot of red albedo versus violet albedo was derived from the Viking Orbiter approach photography (McCord et al., University of Hawaii). The differences were attributed to rock-soil mixes and condensates and tentative correlations of the R-V units with units identified from telescopic spectra, which mostly resemble those of oxidized basalts, were made. A related, but more detailed, study (E.L. Strickland, Washington University) correlated colour variations seen in orbital pictures of the Chryse region with colour variations observed around Viking Lander 1, and constructed an elaborate stratigraphical sequence to explain their apparent superpositions.

Several papers were concerned with eolian processes. R.E. Arvidson of Washington University pointed out that

despite an active eolian regime on the planet, the survival of craters on relatively ancient surfaces implies that bedrock erosion rates are extremely small (< 10<sup>-7</sup> cm yr-1). The wind-induced changes observed must be due almost entirely to remobilization of relatively loose, friable debris. Wind tunnel experiments (R. Greeley et al., Arizona State University) using a number of different sands and targets, which simulate wind abrasion on Mars, showed that for all conditions, abrasion rates were several orders of magnitude higher than those estimated for Mars. The results can be reconciled. Greeley suggests, if sand on Mars consists mainly of easily destroyed aggregates rather than discrete mineral grains. The aggregates probably consist of relatively soft weathered products, which disintegrate easily and have limited abrasive capability. They are nevertheless capable of saltating and forming dunes which are numerous especially at high latitudes. A somewhat different view of eolian erosion (J. McCauley, M. Grolier and C. Breed, US Geological Survey; F. El Baz, Smithsonian Institution) is that it has taken place extensively in the high northern latitudes of Mars to produce the so-called knobby terrain. On the basis of comparisons with landforms in the deserts of south-west Egypt, they propose that the old cratered terrain was initially eroded by fluvial processes and then the interfluves eroded away by eolian and mass wasting processes to leave the knobby remnants that we now observe.

Apart from volcanic studies and several papers on the Tharsis bulge discussed above, discussion of the bedrock geology was restricted to relatively few topics. Channels remain as controversial as when they were discovered a decade ago, and following papers by H. Masursky, M. Carr and B. Lucchitta (USGS), a lively debate took place on the origin of large channels. with water, ice and wind each receiving support. On two points a consensus is emerging; the large outflow channels (see figure on facing page) have a wide range of ages, and the branching valley networks are mostly very ancient. As to origins, it appears that most large channels are complex and a variety of processes, including catastrophic flooding, glacial scour, wind erosion and later filling by lava, may have contributed to their final form. In a related topic R. Huguenin and S. Clifford (University of Massachusetts) elaborated on their previous suggestion that water sources (oases) exist in the Solis Planum and Hellespontus regions. They suggest that continual loss of water from the regolith to the atmosphere in the equatorial regions causes a slow migration of water from the poles to the equator in the megaregolith below the permafrost. The rates are extremely slow and significant only over millions of years. The ground water is replenished by condensation of water from the atmosphere onto the poles.

Finally, several papers dealt with impact craters and what they might tell us of the nature of the martian surface. In almost all areas more than 20 per cent of fresh impact craters have central pits (W. Hale and J. Head, Brown University). These have been previously ascribed to volatiles in the surface and their ubiquity may indicate the omnipresence of ground ice. In a more elaborate study (K. Blasius and J. Cutts. Science Applications), the distribution of craters with different types of ejecta patterns was mapped and showed a complex dependence of ejecta types on geological unit, latitude and possibly other factors. Experimental simulations of martian ejecta patterns have been conducted (P. Schultz and D. Gault, Ames Research Center) and demonstrate that ejecta ramparts closely resembling those on

Mars can be reproduced by impacts into loose debris in the presence of a moderate atmospheric pressure.

Thus, in contrast to the previous Mars colloquia, emphasis of the geology papers was on surficial processes. This may simply reflect the ease with which the relevant available data can be manipulated. The infrared, colour and chemical data, upon which much of the interpretation of surficial processes rests, are readily handled in the computer. In contrast, interpretation of surface morphology, which more closely reflects the bedrock geology, largely depends on the much longer process of direct visual inspection. Analysis of the enormous volume of Viking Orbiter images to improve our knowledge of the geological evolution of the planet will clearly take many years.

## Mars climate change: where are the petroglyphs?

from Fraser P. Fanale

At one point in the colloquium it was pointed out that petroglyphs illustrating both abundant game and well preserved fragments of ostrich eggs thousands of years old could be found in almost rain-free portions of the Egyptian desert. These were considered indicative of a formerly wetter climate in that currently extremely arid region<sup>1</sup>. By analogy, most of the papers directly aimed at the planet Mars seemed to seek some natural 'inscription' of morphology on the martian surface that might indicate a prior warmer wetter period (or, as we say, a more 'paradisical' period) in martian history. To be currently recognized, such an inscription or morphology would have to be large enough to be identifiable in available Viking Orbiter images.

The candidates most often discussed are the various channels of different sizes and detailed geometry<sup>2-4</sup>. The huge 'outflow' channels (see the figure) are spectacular but seem unconvincing as indicators of a very different past climate at the Mars surface. They lack tributaries and seem to spring at full size from what appear to be collapse features. These and other observations suggest that they burst forth from subsurface water reservoirs dammed up by permafrost<sup>5</sup>. Thus their relationship to global conditions in the Mars surface megaenvironment or at the atmosphere-surface interface may be subtle and indirect, or nonexistent. They could probably form today.

The so-called 'runoff' channels are valleys or gullies which are shorter, but

have well developed tributaries, form regional networks and are more suggestive of regional slow erosion by surface runoff<sup>6</sup>. When this geometry is examined in detail, however, it resembles that caused by headward 'sapping' processes involving subsurface water more than that expected from ordinary rainfall7. Nonetheless, there are two aspects of these 'runoff' channels (evidently 'network' channels would be a safer term) that persist in indicating global climate change. First, the network channels are widely believed to occur only in the oldest terrain on Mars6. Second, they are globally distributed within that terrain. The global distribution suggests that rainfall may have had some role even if sapping was involved as well. Moreover the restriction to the oldest (4.0 billion years?) terrain may be in harmony with theories suggesting that global conditions involving high atmospheric Pco, (ref.8) or a reducing atmosphere would have to be sustained by an atypically high degassing rate, possibly associated with accretion9,10, and that such conditions could not prevail for long in the face of planetary hydrogen loss and removal of CO<sub>2</sub> to form rock-attacking acid. It has been argued, however, that many variables (other than age) may determine channel distribution and that the restriction of any channel type to earliest Mars history has yet to be proved11, while others argue a dominant role for ice12,13 or wind14 in carving the channels. Although a role for wind and ice in modifying the channel morphology is readily conceded, water seems to be required to explain some channel characteristics such as their reliable and familiar tendency to flow

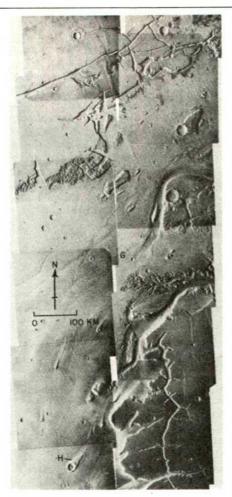

Fraser P. Fanale is in the Planetary Geosciences Section, Institute for Geophysics, University of Hawaii. downhill15.

Besides the channels we have various morphologies indicative of the presence of subsurface H2O ice or even liquid water. One is the so-called 'thermokarst' terrain which resembles the surface distortion and cracking patterns observed in regions of hard frozen (ice-filled) permafrost on Earth<sup>16,17</sup>. Subsurface H<sub>2</sub>O may also be indicated by 'nonlunar' or cohesive flow characteristics in crater ejecta. Most investigators concede that subsurface volatiles are involved in producing such ejecta but disagree as to how many separate categories of 'sloppy' throwout there are, whether or not some types are latitude dependent18,19 and which types require a specific role for water ice, liquid water, adsorbed CO2 and atmospheric CO2. A combined approach which studies the dependence of throwout morphology on crater size, target age and target material, together with experimental cratering in icy and muddy targets - some of which are multilayered - may allow these variables eventually to be sorted out20.

Yet another 'petroglyph' is the 'layered terrain' developed near the edge of the north cap and discovered by the Mariner 1971 mission. Since its discovery, a strong connection between the Mars layered terrain and oscillatory astronomically driven climate change has been indicated21,22. Such a connection, in turn, would conceptually link climate change on Mars to astronomically driven glacial cycles on Earth. Current quantitative models23-26 could be summarized as follows: as the obliquity (angle between rotation axis and normal to the ecliptic) of Mars increases from its present value ( $\sim$ 24°) to its maximum (37°), the increased facing of the polar regions to the Sun will cause warming of these critical regions.

Although the large north cap is now known to be H2O ice, not CO2, and although the CO<sub>2</sub> south residual cap is almost trivial as a CO, reservoir, the atmospheric pressures could possibly double or even triple as a result, owing to desorption of CO2 from large circumpolar and high latitude deposits of weathering products and pulverized igneous rock. When the obliquity falls far below its present value (to  $\sim 11^{\circ}$ ) then the poles cool much more than the regolith which exists at a variety of depths and latitudes, and which experiences a far more attenuated thermal 'wave' (the equatorial regolith even warms). Hence the greatly cooling polar regions will 'cryopump' most of the CO, from the vast 'ocean' of adsorbed CO, in the regolith, resulting in the sudden appearance of a huge CO2 polar cap (as the north cap was originally thought to be), seemingly from nowhere. In the process the atmospheric pressure falls to less than 0.5 mbar.

Thus in the models, the atmospheric pressure varies by a factor of 20 to 100 while giant CO2 caps appear and disappear with the clock-like precision of the

Viking photomosaic of a portion of Kasei Vallis centred at approximately latitude 20°N, longitude 75°W. Outflow features such as streamline hills (H) and grooves (G) occupy the channel floor, but valley sides, tributary canyons and inner channels of the valley floor show pronounced structural control by fracture systems.

From Baker, V.R. & Kochel, R.C. J. geophys. Res. 84, 7961 (1981).

obliquity cycle - a time scale of 105 years. Intuitively it would seem that the harmonic changes in the atmosphere's ability to transport dust and the concurrent variations in cap extent would provide ample means of producing the layered

Current efforts to work out the mechanics of this process take advantage of the fact that the current pressure is just barely enough to raise dust. If pressure decreased by a few millibars, then dust storms would be rare; but if this pressure increased by a factor of two, they might be almost continuous25

Going back further in martian history it is thought that the obliquity cycle was of still greater amplitude before development of the huge Tharsis volcanic complex and associated gravity anomaly. This is because Tharsis near the equator actually stabilizes the planet's axial wobble27; thus the effects discussed would be even more dramatic before Tharsis. Yet investigators keep insisting that the layered terrain is a feature of the latter portion of Mars' history. One solution offered at the meeting is that Tharsis was not formed at the equator, but rather flipped the planet over, causing global wandering of the poles. This could have left several prior 'layered terrains' stranded as outliers about the planet and these could, following erosion, be recognizable only as some sort of blanketing feature of which there are many28. Other solutions involve a steadystate system in which layers are destroyed at the base of the piles as fast as new ones are laid down29. All this provides a marvellous example of comparative planetology since the Earth's climate is affected by the same astronomical mechanism with similar periods but lower intrinsic amplitude and seemingly more complex feedback mechanisms than for Mars (see ref. 30).

The regolith-atmosphere-cap models show that even the more violent regolithatmosphere-cap interaction before Tharsis would, by itself, be incapable of creating a sufficiently profound change in atmospheric CO, pressure or composition to produce a stable greenhouse system that could accommodate rainfall despite the lower energy output of the ancient Sun10,31. Thus a magic additional ingredient that seemingly stabilized a more clement environment early in the history of Mars and produced the infamous channel 'networks' remains unidentified.

In summary, one is tempted to divide

Mars' climate history into three parts. The most recent part would be post-Tharsis (the past about 1 billion years) when obliquity variations force CO2 exchange between the two large CO<sub>2</sub> reservoirs, the regolith and periodically appearing caps, through the conduit of the atmosphere. During this process the atmospheric pressure varies harmonically by more than 20-fold. The previous epoch (4.0 to  $1.0 \times 1.0^{99}$  years?) saw the very same processes dominating, but with larger amplitude due to the absence of Tharsis as a stabilizing influence. Also other 'nonharmonic' or 'irreversible' trends (such as gradual changes in regolith mass, amount of

exchangeable CO<sub>2</sub>, solar constant) may have changed the quantitative aspects of the operation of the three-part system. Finally we have the 'networks' with their fascinating suggestions of an epoch of more clement conditions in earliest martian history. These may require feedback mechanisms such as gas or dust greenhousing or greater atmospheric heat transport to the poles, in addition to the CO<sub>2</sub> exchange. In any event, the networks are found (only) long ago and in another land. The issue of whether or not the wench is truly dead is one best left to the biologists who were not represented among the speakers at the colloquium.

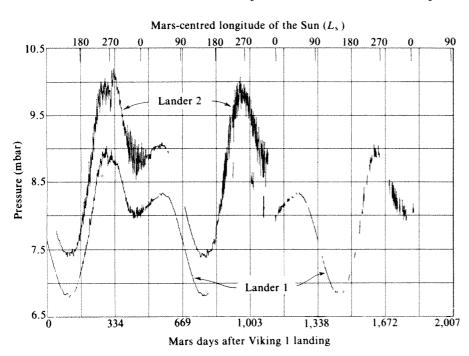

#### The martian lower atmosphere

from Conway B. Leovy

ALMOST three martian years (more than five Earth years) of atmospheric pressure data at two Viking Lander sites have provided a remarkably detailed picture of the weather and climate on Mars. These data, presented at the colloquium by J.E. Tillman<sup>1</sup>, revealed the seasonal shifting of mass between the carbon dioxide polar ice caps and the atmosphere, global circulation changes associated with major dust storms, travelling waves in middle latitudes and intense atmospheric tides driven by absorption of solar radiation in the dust-laden atmosphere.

The seasonal cycling of pressure, involving as much as 30 per cent of the mass of the atmosphere, produces a massive atmos-

pheric movement back-and-forth between the two polar regions, and is indicative of the sensitivity of atmospheric mass to the polar cap radiation balance<sup>2</sup>. Narumi has shown that radiation balance models can account well for the seasonal pressure variations if allowance is made for seasonally varying polar clouds3. The radiation balance is itself highly sensitive to the albedo of the polar caps, and, in a detailed analysis of Viking Orbiter data, D. Paige4 has shown how differences in albedos of the two caps can explain differences in their seasonal behaviour. At the end of summer, there is a small residual cap at each pole: the northern residual is H<sub>2</sub>O ice while the southern is CO<sub>2</sub> ice.

Daily averaged pressures at the Viking Landers. The ordinate interval is the number of Mars days in a Mars year.  $L_s$  values (top) correspond to season: 0, northern spring equinox; 90, northern summer solstice; 180, northern autumn equinox; 270, northern winter solstice. Gaps correspond to missing data.

Paige attributes this difference to the relatively high albedo of the south cap during summer. The seasonal pattern of dust storms provides a likely explanation for cap albedo differences, dust storms being most frequent and widespread during the season of CO<sub>2</sub> condensation on the northern cap. Tillman's data pose a difficulty for this view, however, since they show little or no year-to-year variation in the rates of condensation or sublimation of CO<sub>2</sub> polar ice despite apparently large year-to-year differences in the behaviour of dust storms.

A particularly spectacular global dust storm occurred during Viking's first year. Although several explanations have been proposed for the origin of these global storms, there has been no fully satisfactory quantitative theory of their life cycle, incorporating both storm birth and death. A step in this direction may have been taken by H. Houben<sup>5</sup> who used a highly simplified atmospheric circulation model to show that global-scale atmospheric disturbances can grow if the dust content is non-uniformly distributed and heating is sufficiently intense, but no global-scale disturbances can grow if the dust is uniformly distributed. Since the storms tend to produce a relatively uniform distribution of dust, this could account for storm decay without regeneration of new storms. Further study will be needed to determine whether Houben's model is applicable to the real martian atmosphere.

In another modelling study of dust storms, R. Haberle showed how dust raised in a narrow latitudinal belt, such as the southern summer subtropics, could cause a dramatic intensification and expansion of the thermally driven, zonally symmetric tropical circulation, the so-called Hadley circulation, in both hemispheres6. Tillman's data together with infrared data from the Viking Orbiters showed that such an expansion and intensification of the Hadley circulation actually did occur during the global dust storm observed by Viking. These observations have farreaching implications for the relationships governing the latitudinal extent and intensity of Hadley circulations, in particular, how Hadley circulations depend on such governing parameters as planetary radius, rotation rate and heating intensity. The relationships seem to be applicable not only to the circulations of the 'sister' planets Mars and Earth, but also to the more exotic circulations at the cloud-top levels of Venus and Jupiter.

Martian atmospheric data are also helping to broaden and generalize existing theories of large-scale atmospheric waves. The travelling mid-latitude waves measured by the pressure, wind and temperature sensors at the Viking Lander sites (see the figure) have longer wavelengths

Conway B. Leovy is in the Department of Atmospheric Sciences and Graduate Program of Geophysics, University of Washington, Seattle.

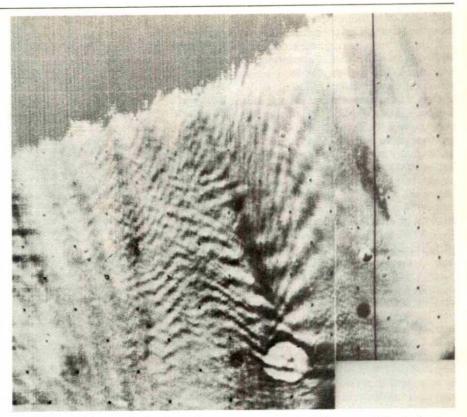

©1981 Macmillan Journals Ltd

and are much more regular than their counterparts, the familiar travelling cyclones and anticyclones of terrestrial mid-latitudes. J. Barnes presented results of efforts to understand the wave properties theoretically7. The high martian static stability and the zonally aligned topography both tend to stabilize these disturbances relative to their terrestrial counterparts, and may be the causes of the great observed regularity. More generally, the scales of the observed waves and those on the other planets seem to fit in with a general scaling for planetary waves similar to that for the Hadley circulations. (See the photograph).

Aspects of the climatic history of Mars are discussed in detail in the preceding article by Fanale. The regolith and CO2 polar ice caps seem to have had crucial roles in buffering atmospheric CO, pressure since the time of regolith formation. The regolith and polar caps also serve as reversible reservoirs of H<sub>2</sub>O. Viking Orbiter measurements of atmospheric water vapour may provide an indication of the relative roles of seasonal adsorption in the regolith and condensation in the polar cap, but the interpretation of these data remains controversial. B. Jakosky and C. Farmer<sup>8</sup> believe that the seasonal variations of H2O are dominated by adsorption, whereas D. Davies and L. Wainio consider exchange with the polar cap to be more important9.

An important new result relevant to the earliest period of atmospheric history was a careful recalculation of the escape flux of nitrogen by J. Fox and A. Dalgarno10. Viking measurements showed an enrichment of 15N with respect to 14N by a factor of 1.7. Fox and Dalgarno were able to show that their calculated escape is consistent with this enrichment and an initial N2 endowment of as few as ten 22 N, molecules per cm2, much more than the current value but substantially lower than the early post-Viking estimate of McElroy et al. 11. The escape flux predicted by Fox and Dalgarno is sensitive to assumed details of the ionospheric structure which have not yet been measured, and to certain other assumptions. If the assumptions are correct, and if the N2/CO2 ratio of Mars is in line with that of the Earth and Venus, the Fox-Dalgarno calculation suggests a total evolved CO, mass equivalent to as little as 50 mbar, but it does not demand such a low

Mariner 9 photograph showing a lee wave system produced by crater Milankovic, a 100-km diameter crater at 53°N, 148°W. The lee waves extend 800 km downstream to the evening terminator with a wavelength of about 60 km.

## Exploration of the upper atmosphere and ionosphere of Mars

from C.T. Russell and A.F. Nagy

STRATEGIES for the exploration of the Solar System and its individual planets have been prepared by a number of different committees and boards. In recent years, the major factor restraining the pursuit of such plans has not been lack of suitable technology but of money or, more specifically, the willingness to spend that money on any particular objective. To establish a logical strategy, the sophistication of the planned investigation and the accessibility of the planet play important roles. Whether sophistication is measured in terms of the type of mission flyby, orbiter, lander, rover or manned or in terms of scientific objectives, the ranking of a particular mission remains roughly the same. Again, whether the accessibility of a planet is measured in terms of the required launch vehicle capability or in engineering considerations such as thermal and power requirements and mission lifetime or in available telemetry rate, one will obtain roughly the same ranking.

The cost of a mission depends on both sophistication and accessibility. For roughly the same cost one could choose to fly a very sophisticated mission to the Moon, a modest mission to Jupiter or a very simple mission to Pluto. The total money available for the planetary program, is, however, limited and choices have to be made. It is sensible to choose a mixture of sophisticated and simple missions, because detailed data obtained from the more accessible bodies can help us to understand the behaviour of the more inaccessible objects, and comparisons between less sophisticated and more fragmented data obtained about a group of planets can be used to learn more about the generalities of planetary evolution. This approach is usually adopted because budgets are tight, and mission planners must seek missions that provide new and exciting data at the minimum cost. However, there are exceptions to this

approach, two of the most major ones being martian and lunar exploration.

Consider for a moment the strategy for exploring a single planet. It appears logical that the initial step should be a reconnaisance with a flyby followed by an orbiter. The flyby would provide snapshots of some characteristics, and the orbiter would give global data over a longer period of time. The instrumentation and objectives of the orbiter will depend on the results of the flyby. It is not obvious that a single flyby or a single orbiter can do the entire job — orbits suited for one objective may be unsuitable for another, for example. Orbiters certainly provide increased observation time, but may also make more sophisticated and/or global measurements possible. Landers provide access to the surface and a longer period for observation and analysis, although at only one site. Sample return provides access to yet more sophisticated analysis as well as allowing longer time for analysis.

Both the United States and the Soviet Union have orbited spacecraft around Mars. The US missions were directed principally towards surface, photogeology and low altitude atmospheric science objectives. The Soviet missions looked at the solar wind interaction with Mars but telemetered little data and had relatively high minimum altitudes that did not penetrate the upper atmosphere and ionosphere of Mars. Hence there is only very limited information on the nature of the upper atmosphere and ionosphere of Mars, little geophysical or geochemical data, only a rough idea of the topography and an essentially unresolved controversy on the existence of an intrinsic planetary magnetic field. Furthermore, the proper global geochemical and geophysical data to plan an intelligent surface exploration strategy are not currently available. The US skipped a stage of exploration in order to be first to return data from the surface. The US and European scientific communities have become aware of this void and are coming forward with proposals to fill the gap. An ESA mission, KEPLER, has been proposed but unfortunately it competes with the Polar Orbiting Lunar Observatory (POLO), also in the planning process at ESA, which is designed to fill the analogous gap in our lunar knowledge. In the US, a Pioneer class Mars Orbiter mission, in many ways similar to KEPLER, has been discussed, but the chances for such a mission are very uncertain given the present tight financial situation at NASA.

In view of this lack of data there was little discussion of martian aeronomy or the solar wind interaction at the conference. J.A. Slavin (UCLA) addressed the existence of a planetary magnetic field. The few cases in which the Soviet Mars orbiters were claimed to enter either a martian magnetosphere or magnetotail are subject to varying interpretations. How far does the bow shock stand off of the planet and what size object would be necessary to create a

Photograph of Mars taken from a distance of 419,000 km by Viking 2. Near the top is the volcano Ascraeus Mons, with a white water-ice cloud to the north-west. The Valles Marineris is visible below the volcano, and the impact crater of the Argyre Basin, covered with winter frost, at the bottom of the photograph. The picture below shows the horizon of Mars with clouds, thought to be crystals of CO<sub>2</sub>, 25–40 km above the surface. Taken 11 July 1976 by Viking Orbiter 1.

bow shock in this position? Slavin showed that a size slightly larger than the planet plus its ionosphere is necessary and thus he feels there is a weak intrinsic field with a moment of about  $1.4 \times 10^{22} \, \mathrm{G}$  cm<sup>-3</sup>, about 5,000 times smaller than the Earth's moment. Examining available ionospheric data, principally from radio occultations, he finds no evidence for a Venus-type interaction. On the other hand, at altitudes above the ionosphere there are similarities in that heavy ions are found to be carried

away by solar wind from both planets.

The lack of martian aeronomical data is particularly intriguing to planetary scientists because of the contrasts between Venus, Earth and Mars. Earth and Mars have similar rotation periods. Venus and the Earth have similar gravitational fields. Mars and Venus have similar atmospheric composition. Venus has no - or at least no detectable - planetary magnetic field while Mars has at most a weak one. In view of these contrasts, will the martian thermospheric temperature be controlled by solar EUV like the Earth's or be rather insensitive to solar EUV like that of Venus? Does Mars have a strong upper atmospheric wind system like Venus?

The ionosphere of Mars is similarly an enigma. Is there a solar wind source of heat as on Venus? What maintains the nightside ionosphere revealed by radio occultation? The terrestrial ionosphere is partially maintained at night by the large reservoir in the magnetosphere that fills with plasma during the day and empties at night. On Venus the night ionosphere is maintained by rapid flows from the dayside and by energetic particle bombardment from the wake of Venus. Finally, the chemistry of the martian ionosphere is a virtual unknown. The neutral atmospheric composition and hence the ionospheric composition are expected to be similar to that of Venus. However, the reaction rates are temperature and velocity dependent and therefore quite a few surprises may be in store.

Venus was found to have an extended non-thermal hydrogen and oxygen corona even though it has a very low exospheric temperature; the presence of this corona is due to dissociative recombination and charge-exchange reactions. On the other hand the Earth has an extensive hydrogen corona caused by the Jean's escape flux and charge-exchange processes, but it does not have a significant oxygen corona. The solar wind is deflected by the terrestrial magnetosphere so there is little significant interaction with the geocorona, but in the case of Venus, with no intrinsic field, the situation is very different, in that there is significant absorption by the corona through ionization in and charge-exchange with the flowing solar wind. In this regard Venus acts very much like a comet. Does Mars behave the same way, or is its corona shielded from the solar wind by a small magnetosphere?

These questions and many more must wait until we get back to a logical series of explorations, for despite the sophistication of some of our knowledge about Mars we are completely ignorant about some of its basic features. Our best hope is ESA's KEPLER or NASA's Pioneer Mars Orbiter missions. The realization of either of these missions would provide a big step forwards in our knowledge of Mars, as well as exposing many areas of ignorance to stimulate further progression in our exploration of the planets.

# The role of gene dosage and genetic transpositions in carcinogenesis

### George Klein

Department of Tumor Biology, Karolinska Institutet, S-104 01 Stockholm, Sweden

Analysis of chromosome translocations associated with B-cell derived tumours and studies of chromosome-15 trisomy in murine leukaemia support the theory, emerging from recent work on tumour viruses, that cancer can be associated with DNA rearrangements which result in the increased expression of normal cellular genes.

IN a recent review on the origin of human cancers, Cairns<sup>1</sup> suggested that most human cancers result from genetic transpositions, rather than mutations. The purpose of the present discussion is to review some of the evidence dealing with the role of specific translocations in the genesis of certain human and animal tumours. Recent findings on mouse plasmacytoma and human Burkitt's lymphoma suggest that the translocations frequently associated with these tumours may act through the activation of specific gene(s) that regulate the growth and differentiation of the lymphocyte-plasmacyte series. It is suggested that translocation of the relevant chromosome segment to an immunoglobulin determinant-carrying region brings the gene(s) under the influence of a highly active cellular promoter, leading to increased expression of the gene product. It will be further argued that increased gene expression is the cause of murine leukaemia associated with trisomy, although in that case the gene may also be altered by mutation or viral promoter insertion. The general theme, that cell transformation is the result of an increase in the expression (or functional activity) of a normal cellular product, will be considered in the light of existing knowledge about the action of virally transmitted, cell-derived oncogenes.

#### Viral oncogenes

Retroviruses: The rapid expansion of viral oncology during the 1960s was considerably motivated by the expectation that specific, virally coded genes determine the synthesis of transforming proteins. This turned out to be true in one sense, but the situation is quite different from what was expected. In several cases, the transforming proteins associated with the directly acting retroviruses are similar to normal cellular constituents, amplified in amount and/or changed in functional activity. All viruses of this category share the following properties:

- First, they can induce tumours in susceptible hosts in vivo after short latency periods.
- Second, they transform cells in vitro.
- ◆ Third, the viral genome carries sequences that appear to have been derived from the normal host genome ('oncogenes'). In most cases, they are inserts that replace large portions of the viral genome. Consequently, the virus becomes defective and requires a helper for replication. Retrovirus-carried transforming sequences are known to be present in all normal cells of the species of origin; corresponding, highly conserved sequences were found in foreign and sometimes quite distant species (see ref. 2). Different transforming retroviruses of the same species often carry partially or wholly different cellular sequences³, suggesting that specific cell-derived sequences could be related to specific forms of transformation³.
- Fourth, retrovirus-carried oncogenes code for transforming proteins, now well defined in several systems. The pp60<sup>src</sup> of Rous sarcoma virus (RSV)<sup>4</sup> and the p120 of the Abelson virus are among the best known examples. Although they are very

different proteins, they share an unusual protein kinase activity, leading to the preferential phosphorylation of tyrosine. It has been suggested that they may act by modifying one or more cellular polypeptides<sup>6</sup>, the identity of which is being extensively investigated. At least a portion of the pp60<sup>src</sup> and the Abelson p120 protein is associated with the cell membrane; proteins of the cytoskeleton are among the obvious candidates (for review see ref. 7).

Although intriguing, tyrosine phosphorylation cannot be regarded as a universal mechanism of transformation, as mouse cells transformed by Kirsten and Moloney sarcoma virus or SV40 virus show no increased abundance of phosphotyrosine<sup>6</sup>. Also, there is no evidence that the transforming proteins of the defective avian leukaemia viruses (DLVs) have any kinase activity. These agents have been divided into three classes8: erythroblastosis, myelocytomatosis (in vitro macrophage transforming) and myeloblastosis-type viruses. Some of these viruses have other transforming effects in addition to that indicated by their name (for details see ref. 3). The oncogenes of the three virus groups, designated erb, mac and myb, represent sequences that have been highly conserved through the phylogeny of higher vertebrates and they are unrelated to the src gene of RSV<sup>3</sup>. They are transcribed in normal cells, but at a much lower level than in transformed cells. There is a strict correlation between the presence of erb, mac and myb sequences, and the ability of the virus to transform erythroblasts, macrophage-like cells or myeloblasts. Studies using temperature-sensitive mutants<sup>9</sup> have shown that a virus-encoded protein is required to maintain the undifferentiated state of transformed erythroblasts. It has been suggested that the DLV-carried oncogenes represent normal cellular genes, coding for lineage-specific proteins involved in the control of haematopoietic differentiation. This would explain the target cell specificity of the DLVs, and suggests that the oncogene product has to be expressed continuously to maintain the differentiation block.

Recently, Hayward et al. 10 found that the slow-acting, non-defective, non-transforming avian leukosis virus (ALV) activates the cellular counterpart of the virally transmitted myc sequence, c-myc. Like other proviruses, ALV integrates randomly with the host cell genome, but occasionally it becomes inserted immediately upstream from the c-myc gene. The viral promoter, included in the long terminal repeat (LTR) sequence at the 3' end of the provirus, has been shown to be responsible for the enhanced expression of c-myc. RNA transcripts have been identified that contained both viral LTR- and c-myc-encoded information and are present at levels 30- to 100-fold higher than the corresponding c-myc RNA of the normal cell.

The 'promoter insertion model', proposed on the basis of these findings, is potentially of great interest. It suggests that a non-transforming, chronically acting virus may cause leukaemia by altering the expression of a normal cellular gene. It also raises the question of whether the activation of *c-onc* genes may

provide a common denominator between the carcinogenic action of viral and non-viral agents. I shall return to this topic in a later section dealing with the tumour-associated translocations.

The examples considered so far all suggest that overproduction of a normal cellular protein, rather than the appearance of new proteins that specifically cause transformation, is the mechanism of retroviral transformation. Is it now possible to disregard the main alternative explanation that postulates the existence of small differences between the viral oncogene product and the corresponding normal cellular product? This can only be answered from a few cases at present. The most convincing evidence comes from the joining of the normal cellular counterpart of a murine sarcoma virus oncogene (mos) with the flanking viral sequences required for infection, transcription and integration. Transfection of appropriate target cells resulted in typical transformed foci<sup>11,12</sup>, supporting the , supporting the view that retroviral transformation is not due to qualitative differences between the cellular and viral oncogene products. This conclusion was further supported by the finding that the transforming gene of a mouse sarcoma virus shows almost complete sequence homology with its cellular homologue<sup>13</sup>

If it is correct that the viral oncogene products are closely similar or identical to corresponding normal cellular proteins, but made in excessive quantities and/or in the wrong place or time, a variety of mechanisms may be explored to explain their actions. All the mechanisms start from the thesis that host-cell feedback regulations are delicately balanced and may be disrupted by relatively small changes. This may be only the first step towards fully autonomous tumours. Most naturally occurring tumours evolve by stepwise progression, and virally initiated tumours are no exception<sup>14</sup>. Autonomy, the degree of independence from growth controlling factors, is not an absolute notion—the initial transformation event may represent only a first step, and sequential modifications may lead to increased tumorigenicity.

DNA tumour viruses: These differ from the retroviruses in some fundamental respects. Whereas the retrovirally transmitted oncogenes represent an unnecessary burden as far as the viral cycle is concerned, the transforming information of the DNA tumour viruses is essential to the viral replication cycle. Moreover, while the productive cycle of the RNA tumour viruses does not interfere with cell multiplication, DNA virus replication is incompatible with cell survival, and as a consequence, the transforming information must be an early product of the viral genome. Considerable progress has been made in identifying the transforming proteins of the small papovaviruses, SV40 and polyoma.

In the SV40 system, large T antigen is the main candidate transforming protein, alone or with small T ('small t') antigen<sup>15,16</sup>. The understanding of its function is complicated by the fact that it is also involved in regulating the late viral replication cycle. Large T binds to the origin of viral DNA replication and also inhibits the synthesis of early mRNA. In microinjection experiments, a critical amount of large T antigen was required before viral DNA replication and the synthesis of virion antigens could take place<sup>17</sup>.

How can a product that must have evolved to promote the late part of the viral cycle, also be a transforming protein? One clue may be provided by the important observation of Lane and Crawford<sup>18</sup> that SV40 large T antigen is complexed to a cellular 53,000 molecular weight (53 K) protein in the nucleus of the transformed cell. A closely similar, and probably identical, 53 K protein has subsequently been found in a wide variety of transformed and tumour cells, including chemically induced mouse sarcomas, spontaneous teratocarcinomas, Abelson virus induced B-cell leukaemias, adenovirus-transformed cells and a variety (but not all) of other transformed or tumour-derived cell lines of murine and human origin<sup>19-27</sup>. Small amounts of 53 K protein were also detected in some normal mouse tissues<sup>20</sup>. A comparison of turnover rates suggests that the role of the SV40 large T antigen in transformation may relate to its ability to

stabilize 53 K<sup>20</sup>, leading to constitutively high expression. The ability of large T antigen to promote the late viral cycle would be rendered unimportant by the fact that transformation usually occurs in non-permissive cells. The ability of large T to trigger host cell DNA synthesis may also be important<sup>15</sup>.

The proposed role for the large T antigen-53 K complex in transformation received unexpected independent support from studies of an entirely unrelated transforming DNA virus system, the Epstein-Barr virus (EBV). The only virally induced product that is regularly found in EBV-transformed cells, the nuclear antigen (EBNA)<sup>28</sup>, was found to consist of a virus-specific 48 K subunit, complexed with 53 K of cellular origin<sup>29,30</sup>. A similar (probably identical) 53 K protein, not complexed to 48 K, was also present in some EBV-negative B-cell-derived lymphoma lines, but in smaller quantities than in the EBV-carrying lines. EBV conversion of these lines into stably EBNA-positive variants increased their content of 53 K protein<sup>30</sup>.

The way in which EBV results in transformation is virtually unexplored. As EBNA is always associated with transformation and is the only virally determined product known to be expressed in transformed cells, it is likely to have a key role. Recently, non-permissive cells devoid of EBV receptors have been successfully infected with EBV by microinjection<sup>31</sup> or by implantation of EBV-receptor-carrying membranes<sup>32-34</sup>. In such cells, little or no EBNA is produced and the virus enters directly into the lytic cycle. It is thus intriguing to speculate that the appearance of the EBNA-53 K complex is involved in transformation and may even prevent the cells from entering the lytic cycle. To further explore the possible role of 53 K in transformation and/or tumour progression, comparison of cell populations that have reached different stages in progression will be of considerable interest.

One such system can be provided by infecting certain EBV-negative human B-cell-derived lymphomas with EBV. This leads to a decreased serum requirement, increased resistance to saturation conditions, changed lectin agglutinability and capping behaviour and increased cloning efficiency in soft agarose 35-40, and is accompanied by a parallel increase in the amount of 53 K<sup>30</sup>. As another example, the serial propagation of SV40-transformed cell lines, an exercise in *in vitro* progression, tends to favour the selective amplification of the DNA sequences coding for large T antigen 15.41. As the amount of large T antigen and 53 K protein were found to vary in parallel 15.18.20.42, the corresponding increase in the amount of the 53 K protein may have an important selective role.

Despite their extensive functional and structural homology, the transforming functions of SV40 and polyoma virus seem to be very different. For polyoma, there is extensive evidence from both genetic and DNA transfection studies that large T is neither necessary nor sufficient for transformation<sup>43</sup>. In all probability, middle T, alone or together with small T, is responsible for the transforming function, Middle T is a 56 K protein coded by the early region of the viral genome. It shares its N-terminal region with large T but is otherwise very different, as a result of splicing of the mRNA precursor and subsequent frameshift. Like pp60<sup>src</sup>, middle T binds to the inner surface of the cell membrane and is associated with protein kinase activity<sup>43,44</sup>. There is no corresponding antigen in the SV40 system.

It has been suggested that part of the middle T sequence has originated from the host genome<sup>45</sup>, but the evidence is inconclusive. Polyoma middle T therefore still remains the most likely candidate for the role of a virally coded transforming protein. This conclusion is also supported by the fact that while polyoma-transformed cells contain the cellular 53 K protein<sup>18</sup>, it is present in an ~10 times lower concentration and is not bound to polyoma T antigen (L. Crawford, personal communication).

In conclusion, the two best known transforming DNA tumour viruses, polyoma and SV40, use very different strategies in transforming cells. For polyoma, there is a possible analogy with the transforming retroviruses insofar as transforming middle T protein has kinase activity and is associated with the inner part of the plasma membrane. For SV40, a very different mechanism,

stabilization of the transformation-related cellular 53 K protein by large T, may have a crucial role, particularly since a very similar complexing and stabilization occurs in an unrelated, but highly transforming herpesvirus, EBV.

#### Trisomy in murine leukaemia

All known murine leukaemia viruses, except the Abelson virus, are non-defective, lack direct transforming activity *in vitro*, carry no cell-derived sequences and induce leukaemia only after long latency periods. Their oncogenic effect is often dependent on prolonged viraemia and is heavily influenced by the genetics of the host<sup>46</sup>.

Most virally and non-virally induced murine T-cell leukaemias are chromosomally abnormal. Trisomy of chromosome 15 is the dominating and often the only change 47-50. Other trisomies (for example, trisomy 17) occur more rarely and usually represent an additional change to trisomy 15<sup>47,50</sup>. Trisomy 15 has also been found in B-cell lymphomas, often together with other chromosomal changes 51,52. Chromosome 15-trisomic leukaemias have been induced by Moloney virus 49,53, radiation leukaemia virus 47 (Fig. 1), X-ray radiation 4 and various chemical carcinogens 48,55,56. Most spontaneously arising AKR leukaemias were also trisomic for chromosome 15<sup>57</sup>. The cytogenetic analysis of T-cell leukaemias induced in mice carrying various types of chromosome 15 translocations has led to the conclusion that the critically important region that tends to be duplicated in the course of leukaemogenesis is localized in the distal region of the chromosome

Is the duplication of chromosome 15 a secondary consequence of leukaemogenesis, or is it directly involved in causing the transition from the preleukaemic to the leukaemic state? According to the former alternative, it could be imagined that only 15-trisomic leukaemia cells can survive among all trisomies generated by non-disjunction whereas the others are lethal. This possibility could be excluded by banding analysis of chemically (dimethylbenz(a)anthrene) and virus (Moloney) induced T-cell leukaemias, derived from three different mouse stocks, carrying different Robertsonian translocations<sup>50</sup>. The translocations were derived from the centromeric fusion of chromosome 15 with another large autosome (chromosomes 1, 5 and 6, respectively). The trisomic leukaemias contained three copies of the translocation chromosome, in most cases the only detectable chromosomal anomaly. This can only mean that the leukaemiaassociated duplication of chromosome 15 is an important event in leukaemogenesis, as it compels the centromerically fused large autosome to become a 'fellow traveller'. It also shows that the trisomy of the attached autosome is by no means lethal for the leukaemia cell.

How does trisomy 15 contribute to leukaemogenesis? Consider the AKR mouse strain, inbred and selected for high leukaemia incidence. At least four independent genetic systems are known to favour leukaemia development in this strain: (1) the integrated ecotropic (Gross-subtype) proviral DNA, localized at two sites in the genome, Akv-1 and Akv-2 (ref. 46); (2) the Fv-1<sup>n</sup> amplification system that promotes virus production<sup>59</sup>; (3) the H-2-linked Rgv-1<sup>s</sup> gene<sup>60</sup>, believed to be responsible for the deficient immune response of the AKR mouse to the leukaemia-associated antigens; and (4) a less clearly defined system that increases the likelihood of the leukaemic change directly at the level of the T cell<sup>61,62</sup>. In spite of these multiple leukaemia-favouring mechanisms, leukaemias appear only after a long latency period, in middle-aged or old mice, and are frequently trisomic for chromosome 15<sup>57</sup>.

One reason for the long latency period may lie in the requirement to generate recombinants between eco- and xeno-tropic C-type virus. Such recombinants are believed to bear a more direct responsibility for leukaemia induction than the ecotropic virus by itself<sup>63</sup>. The generation of trisomy-15 by random non-disjunction may be another time-consuming process. The promoter insertion model of Hayward *et al.*<sup>10</sup> may be considered as a third possibility. These alternatives are not

Fig. 1 G-banded karyotype and metaphase plate of leukaemia cell originating from the thymus of a male C57BL/6 mouse inoculated intrathymically with A-RadLV (radiation leukaemia virus)-induced preleukaemia cells. Note the presence of trisomy 15 (arrows).

mutually exclusive; they may represent complementary events, acting synergistically or in succession. One may envisage a broadening of the host range by recombination, leading to the reinfection of a large number of potential target cells. Random integration of the reinfecting viral genome would have no leukaemogenic consequence until the appropriate oncogene happens to be activated by the rare event of integration of the viral promoter in its neighbourhood. Duplication of the chromosome that carries the activated oncogene would help to overcome the influence of a *trans*-acting regulator, coded by the normal homologue, and experimental evidence supporting this is summarized below.

Genetic studies on the mechanisms of murine leukaemogenesis have shown that part of the genetic variation between high and low leukaemia strains acted at the level of the target T lymphocyte itself. This information came from experiments where normal thymus tissue from a high and a low leukaemia-prone strain was transplanted to the common, thymectomized F<sub>1</sub> hybrid host. Despite the fact that they were in a common host environment, exposed to the same immunological and viral influences, the thymocytes of the high leukaemia strain became leukaemic more frequently than did the cells of the low leukaemia strain<sup>61</sup>.

Analysis of trisomy 15 in leukaemias arising in  $F_1$  hybrid hosts, and related somatic hybrid studies, suggest that chromosome 15-localized gene(s) may influence the likelihood

of transformation at the target cell level. We have found  $^{55,56}$  that T-cell leukaemias induced by dimethylbenz(a) anthracene or Moloney virus in  $F_1$  hybrids derived from crosses between two mouse strains with cytogenetically distinguishable 15-chromosomes, show a highly asymmetrical trisomy. In most crosses, one of the two parental 15-chromosomes was duplicated preferentially, depending on the strain combination.

For a given genotype, the preference was the same for the virally and the chemically induced leukaemias. In crosses where the difference between the parental 15-chromosomes was only morphological but not genetic (for example, CBA×CBAT6T6 or AKR×AKR Rb6; 15) there was no significant preference, showing that the genetic content, rather than the translocated state of the chromosome, was responsible for the asymmetry. Chromosomes 15 derived from different mouse strains showed a distinct hierarchy with regard to leukaemia-associated preferential duplication. As non-disjunction of the two homologous 15-chromosomes must occur with equal frequency, this can only be interpreted to mean that the 15-chromosome-associated gene(s) that influence leukaemia development is subject to a certain variation between different mouse strains. Duplication of one of the chromosomes (in a heterozygote) is more likely to cause leukaemia than duplication of the other.

cause leukaemia than duplication of the other.

Somatic hybrid studies<sup>64</sup> have provided further evidence for the existence and probable nature of this variation. A 15trisomic AKR-derived lymphoma, designated TIKAUT, was fused with normal CBA T6T6 fibroblasts, carrying a 14; 15 translocation. Resulting highly tumorigenic segregants contained the tumour-derived chromosome 15 in five to six copies, as a rule, instead of the expected three copies. The normal parent-derived chromosome 15 was only present in one copy. Segregants of low tumorigenicity usually contained only two tumour-derived 15-chromosomes and two normal-derived 15-chromosomes. Other autosomes showed only minor random variations around the expected number, four. This suggests that the normal and the tumour-derived 15-chromosomes differ in their genetic content; the former has elements that favour and the latter that inhibit tumorigenicity in the syngeneic host. We must postulate that the duplicated chromosome 15 in the original tumour, as well as the amplified chromosome 15 in the somatic hybrid, carries a mutated form of a gene that normally controls lymphocyte growth and differentiation. Alternatively, the same gene may have been permanently activated by proviral DNA insertion. The phenotypic effects of this change would not be expressed, however, unless the chromosome is duplicated by non-disjunction, needed to overcome the suppressive influence of a *trans*-acting regulator, produced by the normal homologous chromosome. This hypothesis can be tested by cytogenetic analysis of segregants of hybrids between 15-heterozygous trisomic leukaemias and normal cells. If the hypothesis is correct, only the duplicated chromosome will be amplified in highly tumorigenic segregants.

#### **Translocations**

While the vast majority of human and animal tumours fail to show specific translocations, highly regular translocations are associated with chronic granulocytic leukaemia in humans (Ph<sub>1</sub> chromosome), with Burkitt's lymphoma and with murine plasmacytomas. This review has been limited to the latter two, B-lymphocyte-derived tumours.

Two characteristic translocations have been found in mineraloil-induced murine plasmacytomas  $^{65,66}$ . The more common marker, seen in both  $\kappa$  and  $\lambda$  producers, arises by the translocation of the distal part of chromosome 15 to chromosome 12, known to carry the heavy chain immunoglobulin locus (Fig. 2). The breakpoints are D3 in chromosome 15 and F2 in chromosome 12. The heavy chain immunoglobulin loci are located proximally to band F2<sup>67</sup>.

A reciprocal 6; 15 translocation was also seen but only in  $\kappa$  chain-producing plasmacytomas<sup>65,66</sup> (Fig. 3). Chromosome 6 is known to carry the  $\kappa$  chain locus<sup>68</sup>, although its precise location is unknown. The breakpoint on chromosome 15 was in band D3, as in the 12; 15 translocation.

In diploid or near-diploid tumours, the translocations only affected one of the two homologous chromosomes. In tetraploid plasmacytoma cells, the translocation must have occurred before polyploidization, because two of the four homologous chromosomes showed the translocation.

In each plasmacytoma clone only one of the two homologous immunoglobulin loci is responsible for the synthesis of a complete immunoglobulin molecule. It is of great interest to explore whether or not the translocation selectively affects the active or the inactive chromosome 12. This can be done by correlated cytogenetic and immunoglobulin allotype studies on plasmacytomas heterozygous for the allotypic marker and for an appropriate Robertsonian translocation.

The segment of chromosome 15 involved in the plasmacy-toma-associated translocations is localized within the region that becomes regularly duplicated in the 15-trisomic B- and T-cell leukaemias (including cases where parts of chromosome

Fig. 2 G-banded karyotype of a hypertetraploid plasmacytoma cell. Note the presence of two copies of the T(12; 15) translocation and two deleted 15 chromosomes (del 15).

Fig. 3 G-banded karyotype of a hypertetraploid plasmacytoma cell. Note the presence of two copies of the reciprocal translocation between chromosomes 6 and 15 (rcpT (6; 15)).

15 are translocated to other chromosomes)<sup>49,58</sup>. It is likely that this region carries gene(s) that control lymphocyte-plasmacyte differentiation and growth. Translocation to the immunoglobulin gene region, an area that is highly active in B lymphocytes and plasma cells, may bring the gene(s) under the influence of a highly active promoter. This could lead to the overproduction of some important regulator, in a manner analogous to retrovirally mediated oncogene transmission and the viral promoter model. It is important to explore whether the breakpoint on the immunoglobulin-locus-carrying chromosome affects the same nucleotide sequences in different tumours and how it is related to the immunoglobulin locus itself.

If studies of this type confirm that the translocation affects a specific site within or near the immunoglobulin locus, one may still ask whether this is due to some special vulnerability of this region to breakage, due to the DNA rearrangements that are known to occur in the area. This is unlikely, however, because  $\lambda$ -producer plasmocytomas showed only 12; 15 but no 6; 15 translocations<sup>69</sup>, even though the  $\kappa$  region is known to be deleted or rearranged in  $\lambda$  producers<sup>70</sup>.

The promoter activation hypothesis also implies that the translocation of the distal part of chromosome 15 to the immunoglobulin-locus-carrying chromosomes, rather than the deletion from 15, is responsible for the malignant transformation. This hypothesis can be tested by parallel chromosome segregation—tumorigenicity studies on appropriately constructed somatic hybrids.

A possibly analogous translocation has been discovered in a human B-cell-derived tumour. Both the EBV-negative and the EBV-carrying forms of Burkitt's lymphoma were found to carry a highly specific reciprocal 8; 14 translocation<sup>71-73</sup>. Banding analysis showed the involvement of the same breakpoints in different individual cases, affecting bands 8q24 and 14q32. The same translocation was also found in B-cell-derived acute lymphocytic leukaemia<sup>74,75</sup>, believed to originate from the same type of target cell as Burkitt's lymphoma. Other lymphomas were also found to carry 14q + markers in a considerable number of cases, but the variability of the breakpoints and of the donor chromosome distinguish these markers from the specifically Burkitt's lymphoma-associated 8; 14 translocation<sup>76</sup>.

Recently, variant forms of the Burkitt's lymphoma translocation have been described. In these cases, the same distal piece of chromosome 8 becomes translocated, but to chromosome 2 or 22 rather than chromosome 14<sup>77-81</sup>. The situation is reminiscent of the Philadelphia chromosome, where

a 22; 9 translocation is found in most cases, while a minority  $(\sim 10\%)$  shows a 22-deletion with the same breakpoint, but with either no identifiable translocation site or a translocation to other recipient chromosomes<sup>82</sup>.

The variant Burkitt's lymphoma translocations suggest that the distal part of chromosome 8, rather than chromosome 14, carries the gene(s) responsible for the development of Burkitt's lymphoma. As chromosome 14 is known to contain the immunoglobulin heavy chain loci in man<sup>83</sup>, the human 8; 14 translocation may be functionally analogous to the murine plasmacytoma-associated 12; 15. This concept is strongly supported by the recent demonstration<sup>84</sup> that the human  $\kappa$  gene is on chromosome 2, and the  $\lambda$  gene on chromosome 22—the chromosomes involved as recipients of the distal chromosome 8 fragment in the variant Burkitt's lymphoma translocations. Interestingly, the  $\kappa$  gene has been localized to the short arm of chromosome 2, in the same region as the breakpoint involved in the 2; 8 translocation.

#### Perspectives

Two major alternatives are now under consideration to explain the action of the virally transduced, cell-derived oncogenes. According to one hypothesis, transformation is merely a matter of gene product dosage. Due to the integration of the oncogene in the wrong place or in the wrong cell, a certain normal cellular product is synthesized in excessive quantity or at the wrong time, interfering with the normal differentiation programme. The second alternative predicts the existence of subtle qualitative differences between the virally carried oncogene and the corresponding normal cellular gene.

While the problem cannot be regarded as definitely settled, the recent successful transformation of fibroblasts with the normal cell-derived counterpart of the murine sarcoma virus-associated oncogene<sup>11,12</sup>, and even with randomly sheared DNA from normal cells<sup>85-87</sup> argues against the second hypothesis.

For tumour-associated non-random chromosomal changes such as chromosome 15 trisomy it is simplest to invoke gene dose effects. It may be objected that a change in gene dosage of 50% is a relatively minor change. On the other hand, the relationship between the normal cell and its many growth controlling signals must be extremely finely poised, so that small changes may tip the balance and favour unlimited proliferation. However, the chromosomal analysis of high and low tumorigenic segregants of somatic cell hybrids indicates that there also

exists a qualitative difference between the relevant gene(s) carried by the tumour- and the normal cell-derived chromosome 15. This is probably due to a mutation or some other change, like proviral DNA insertion. Duplication of the altered chromosome has probably overcome trans-acting regulation by the normal homologue, resulting in the leukaemic phenotype.

Both quantitative and qualitative effects must be considered in relation to the murine plasmacytoma-associated 12; 15 and 6; 15 translocations. A simple transposition of the distal region of chromosome 15, presumed to be involved in the control of lymphocyte-plasmacyte growth and differentiation, to the highly active immunoglobulin-producing gene region would be in line with the gene product dosage hypothesis, provided it can be shown that the translocation involves the active and not the allelically excluded immunoglobulin-producing chromosome and takes place within or close to the immunoglobulin gene region. Alternatively, it is possible that sequence changes ('mutations') are also involved here. Somatic hybridizationsegregation experiments involving parallel cytogenetic and tumorigenicity tests of the same type as on the trisomic lymphomas may give decisive information on this question. The Burkitt lymphoma-associated specific translocations, where the distal fragment of chromosome 8 is translocated to the heavy chain immunoglobulin-cluster-carrying chromosome 14 in typical cases or to the  $\kappa$  light chain gene-carrying chromosome 2 or the  $\lambda$  light chain gene-carrying chromosome 22 in variants, lends strong independent support to the hypothesis. Yet further support comes from the fact that the  $\kappa$  gene is localized in the short arm of chromosome 2, which is precisely where the translocation occurs (band p12).

The constitutive switch-on of cellular oncogenes is emerging as a fairly common theme in carcinogenesis. The evidence is far

from complete and there are already some examples that may not fall into this general category (transformation by some of the oncogenic DNA viruses is one of them). We must be wary of the ever-present occupational risk of the cancer researcher: generalization. With this caveat, it is quite clear that cellular oncogenes can be switched on to constitutive activity by a variety of mechanisms. In the model of direct retroviral transformation, the oncogene is switched on because it has recombined with a powerful retroviral promoter. The resulting unit can transform, no matter where it integrates. This situation is mimicked by the successful DNA-mediated transformation with large pieces of tumour-derived DNA<sup>86</sup>. In other situations, the cellular oncogene remains in place, but becomes activated due to events that occur in its immediate neighbourhood. The integration of a viral promoter is one such event, chromosomal translocation to a highly active region of the cellular genome is another. Experimentally, the occasional successful transformation by normal cell-derived small DNA fragments probably mimics the latter situation.

The identification of the oncogenes and the definition of their regulation and function in the normal cell are clearly among the most fascinating aspects of the field. Their high evolutionary conservation strongly suggests that they have essential roles in cell growth and regulation. This analysis has already erased much of the traditional conceptual and experimental barriers between chemical and viral carcinogenesis and will no doubt eventually unite them under the common umbrella of cell genetics.

My studies and those of my colleagues in this area have been supported by grant 2 R01 CA 14054-07A1, awarded by the National Cancer Institute, DHEW and by grant NC-6580 from the Swedish Cancer Society.

# New observational constraints on the M87 jet

J. T. Stocke\*, G. H. Rieke\*† & M. J. Lebofsky\*

\* Steward Observatory, and † Lunar and Planetary Laboratory, University of Arizona, Tucson, Arizona 85721, USA

New observations at 1.6–3.45  $\mu$ m confirm the presence of a dramatic ( $\Delta \alpha \sim 1$ ) break between radio–IR wavelengths and 6,000 Å, in the spectrum of the M87 jet. These data, in combination with data taken in other spectral regions, show that the individual knots in the M87 jet have nearly the same spectral indices and nearly the same large ( $\Delta \alpha \sim 1$ ) spectral break. This large spectral break and the constancy of spectral properties between the knots pose serious constraints for models of the M87 jet.

THE M87 jet has long attracted detailed observational and theoretical interest<sup>1</sup> because of its clear relationship with non-thermal activity centred in the nuclei of galaxies. Recently this object has become the prototype for a myriad of radio galaxies which possess radio (and in some instances optical and even X-ray) jets which clearly link the galactic nucleus to the extended regions of radio emission (for a review see ref. 2).

The M87 jet is unique in that it is easily detectable over a very wide range of frequency  $(10^8-10^{17} \text{ Hz})$  and, therefore, gives us the opportunity to study the distribution of photon energies in some detail. Thus, the overall spectrum of the M87 jet may help to determine the exact manner in which energy is transported from the nucleus to the outer radio emitting regions. We now present new IR observations of the brightest knots in the M87 jet at  $H(1.6 \ \mu\text{m})$ ,  $K(2.2 \ \mu\text{m})$  and  $L(3.4 \ \mu\text{m})$ .

#### New observations

Near IR measurements of the jet of M87 were obtained on the nights of 17 and 18 February 1981, using the Steward Observatory 2.25-m telescope. The seeing on these nights was generally good and in particular was 1 arc s or better during the H measurements. Three different observing modes were used. First at  $K(2.2 \,\mu\text{m})$ , where the flux from the jet dominates the observed flux, consisted of photometry with the aperture centred on knot A, 12 arc s from the nucleus and complementary photometry centred on a patch of galaxy 12 arc s from the nucleus but 180° different in position angle. In the second mode,

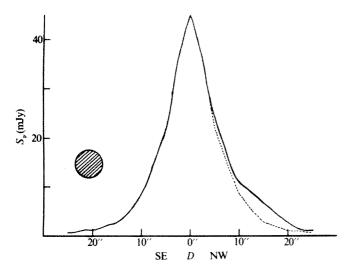

Fig. 1 Scan through the nucleus of M87 from the south-east to the north-west (jet) at  $H(1.6 \mu m)$  using a beam as indicated by the shaded circle. D is the distance from the nucleus. The dashed line on the north-west side is the reflection of the south-east (stars only) scan about the nucleus.

Table 1 IR photometry of	knots $A + B$ in the M87 jet
Wavelength (μm)	Flux (mJy)
H (1.6) K (2.2) L (3.45)	$3.8 \pm 0.2$ $5.1 \pm 0.2$ $7.2 \pm 0.6$

at  $L(3.45 \mu m)$ , where the stellar background makes only a small contribution, photometry on the jet was obtained, and the stellar contribution was estimated from the 2-µm flux of the complementary galaxy patch and assuming that K - L = 0.2. This correction amounted to only 10% of the flux observed at L. The third observing mode was at  $H(1.5 \mu m)$ , where the stellar contribution is comparable with that from the jet, and consisted of scans in the jet and anti-jet directions, registered on the nucleus. The result of this scanning at 1.6 µm is shown in Fig. 1 where the flux from the jet is clearly seen as an excess above the stellar flux. A 5.9 arc s aperture, chopping in declination, and a reference beam displaced 10 arc s in declination from the signal beam were used for all the measurements. The observations were calibrated as described by Low and Rieke3; the zero point of the magnitude scale at H was assumed to be 1,080 Jy. Data at 2.2 and 3.45 µm were taken using a liquid-nitrogen cooled InSb detector while a liquid-helium cooled InSb detector was used at 1.6 μm and to repeat the observations at 2.2 μm. In addition, the stellar contribution at K was checked by estimating the stellar flux at 1.6  $\mu$ m from the scan and assuming that H - K =0.25, the stellar colour appropriate at knot A's distance from the nucleus. This procedure yielded a stellar correction within 20% of the value observed from the complementary galaxy patch. These results are listed in Table 1.

# Comparison with observations at other wavelengths

Before these IR observations, there was still some question as to whether the radio emission from the jet arose from the same physical source as the optical emission. On the one hand recent interferometer maps of the jet by Owens et al.<sup>4</sup> and by Laing<sup>5</sup> strongly argue for a single emission mechanism as they demonstrate a one-to-one correspondence between the position, size and relative brightness of the radio and optical knots. However, there were lingering doubts about this conclusion because:

- (1) Earlier attempts to connect all the available optical, radio and IR detections and upper limits with a single smooth curve produced a violation or near violation of the  $10~\mu m$  upper limit.
- (2) The optical spectral index of 1.7 is much larger than the radio spectral index of 0.6. The procedure of fitting a smooth curve through the data required a dramatic break ( $\Delta \alpha \sim 1.0$ ) just below the lowest frequency optical observation<sup>7</sup>. Such a large

0028-0836/81/480319--04\$01.00

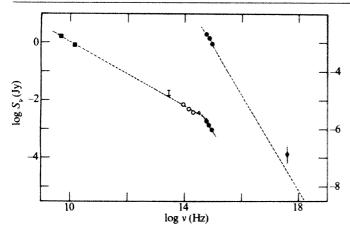

Fig. 2 The spectrum of the brightest knots (A+B) in the M87 jet. The radio ( $\blacksquare$ )<sup>4-5</sup>, IR ( $\bigcirc$ , this paper, 10- $\mu$ m upper limit from ref. 6), optical ( $\triangle$  for I (ref. 7);  $\blacksquare$ , for U, B, V (refs 6, 8, 9)), and X ray ( $\blacksquare$ ) have been normalized to a 6 arc s aperture centred on knot A, 12 arc s west and 5 arc s north of the nucleus. The X-ray point is a flux measurement of the entire jet corrected downwards by assuming a light distribution identical to that seen in the optical  $^{8,12}$ . The left-hand flux scale refers to radio-optical frequencies while the right-hand scale refers to optical-X-ray frequencies. The errors are smaller than the figure symbols except where explicitly shown.

break is twice as large as that expected due to isotropic synchroton losses and continuous particle injection.

Figure 2 shows the spectrum of the region of knots A and B(see ref. 7 for knot identification) including our IR measurements at H, K and L. All of these observations are corrected to a 6 arcs aperture at the position of knot A, 12 arcs from the nucleus. At this position the aperture includes knots A, B, I, and J. The optical observations have been corrected downward by 0.03 mag at each frequency because knot K was included in the 7-arc s aperture used  $(m_B \text{ for knot } K = 18.95 \pm 0.2)^8$ . Only if the positioning of the observing aperture were displaced 1 arcs would knot C be included, requiring an additional 0.25 mag downward correction. That this is not the case is suggested by the agreement between the photoelectric blue magnitude<sup>6</sup> and the photographically determined blue magnitudes<sup>8</sup> of knots A, B, I and J. The point at I (ref. 7) does include knot C and has been corrected downward, but it is still 0.6 mag too high to fit a smooth curve between V and H. It is not surprising that this point is the most discrepant because it is based on photographic photometry near the wavelength where the contrast between the jet and the galaxy is minimal. Note that there is no indication of recent (1964-74) optical variability in knots A and B  $(\pm 0.1 \text{ mag})^{7-9}$  although there is a claim for optical variability on a longer time scale  $(1956-78)^{10}$ .

The radio data are from ref. 5 at 15.4 GHz and ref. 4 at 5 and 15 GHz. At 15 GHZ the values of the peak flux and knot size for knots A and B from ref. 5 yield total flux values 60% higher than similar estimates from the map in ref. 4. We have used the ref. 5 value both because the larger beam size may have included flux missed by the smaller beam of the incomplete VLA and because of the uncertainty in determining peak fluxes from contour maps. From the  $805 \pm 25$  mJy value at U band<sup>5</sup>, we estimated  $1,550 \pm 60$  mJy at C band by using the spectral index between those two bands ( $\alpha = 0.59 \pm 0.08$ )<sup>4</sup>.

We have not plotted the UV data points for the jet from observations made with IUE<sup>11</sup> because there was no attempt to subtract the galaxy's contribution accurately. Although these points are very uncertain, they do suggest a continuation of the optical power law from 3,000 to 1,000 Å without a dramatic change. A recent X-ray point<sup>12</sup> is also consistent with an extrapolated power law of  $\alpha = 1.7$  to within the errors. There is also an indication that the distribution of light in X rays is similar to that in the optical. The high frequency data are thus consistent at present with a single steep power law from  $\log \nu = 14.8$  to 17.6.

The new data for the jet are consistent with a smooth spectrum with internal slopes in the radio, IR and optical of 0.6, 0.8 and 1.7. The point at I (ref. 7) is not consistent with this spectrum, but the 10 µm upper limit is no longer violated. If we demand that the extrapolation of the IR data points to higher frequencies fall above or at the point at V (ref. 6) then the IR slope must be  $0.7 \pm 0.1$ . Thus, the data now argue strongly that the radio and IR emission mechanism is the same because the measurements in both spectral regions connect up with a simple smooth curve of nearly constant slope. In fact, the present observations are still consistent with a single power law below the optical with  $\alpha = 0.7$ , although there is a slightly better fit with a gently curving spectrum steepening from 0.55 to 0.7. Either case requires a dramatic break between IR and optical and further constrains the spectrum so that a break of  $\Delta \alpha \sim 1$  most probably occurs between 5,500 and 6,500 Å and certainly within the range 4,500–8,000Å. The slope from  $H(1.6 \mu m)$  to Vis 0.6, indicating that the break cannot be far from V

The spectral break could be due to reddening, but this seems improbable because: (1) the IUE data<sup>11</sup> show no evidence for the 2,200 Å dust feature in the jet; (2) without any dereddening being applied, the V point lies slightly above the extrapolated power law from the IR—dereddening will increase this difference; (3) scans along the jet indicate spectral properties which are constant along the jet so the extinction along the jet would have to be uniform over many kiloparsecs; (4) internal reddening has not been observed in elliptical galaxies.

The scan in Fig. 1 can be used to derive the IR brightness along the jet. Figure 3 shows the results of a point-by-point subtraction in the form of a strip scan along the jet with 6 arc s resolution. The data (solid line) are compared with similar data at 15.4 GHz (ref. 5) and in the optical U filter. A similar optical scan in the B filter. is identical to within the combined 3% errors with the U filter data. We have plotted only the U filter data as its errors are slightly smaller due to the higher contrast of the jet at that frequency and to the use of a linear detector in that data set. No data are plotted inside 10 arc s from the nucleus where the galaxy subtraction causes much larger errors at optical and IR frequencies.

To within the combined errors all four scans are identical indicating extremely similar spectral indices all along the jet. Table 2 lists the radio–IR (low  $\nu$ ) and IR–U filter (high  $\nu$ ) spectral indices for the four brightest knots outside 10 arc s from the nucleus. To within quite small errors the spectra both above and below the break are identical for all four knots.

Even though no scan is available at V band, these data strongly suggest that the break frequency is identical for all four knots to within  $\pm 0.3$  in  $\log \nu$ .

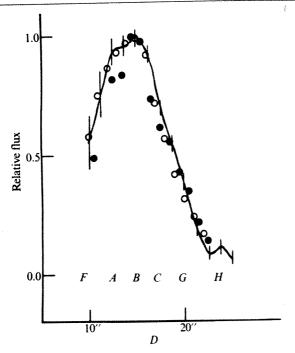

#### New constraints on jet models

These new IR observations place severe restrictions on any successful model of the M87 jet.

- (1) The optical and radio emission almost certainly arise from a single emission mechanism.
- (2) The break in the spectrum of the brightest knots is very abrupt in frequency ( $\Delta \log \nu \le 0.1$ ) and large ( $\Delta \alpha = 1$ ).
- (3) The spectra of the various knots are very similar both above and below the break frequency.
- (4) The break frequency must be nearly identical (to within 0.3 in  $\log \nu$ ) for the brightest knots.

Table 2 Spectral indices in the M87 jet						
Knot	$lpha_{ m low}$	$lpha_{ m high}$	λ <sub>break</sub> (Å)			
Α	$0.57 \pm 0.01$	$0.92 \pm 0.04$	5,500-6,500			
В	$0.58 \pm 0.01$	$0.93 \pm 0.05$	4,500-6,500			
C	$0.58 \pm 0.01$	$0.92 \pm 0.05$	4,500-6,500			
G	$0.58 \pm 0.02$	$0.88 \pm 0.09$	4,500-8,000			

 $\alpha_{\mathrm{low}} = \alpha(H~(1.6~\mu\mathrm{m}),~5~\mathrm{GHz});~\alpha_{\mathrm{high}} = \alpha(U~(0.36~\mu\mathrm{m}),~H~(1.6~\mu\mathrm{m})).$ 

1337

Fig. 3 Comparison of the flux distribution along the jet at three wavelengths:  $\operatorname{radio}^5(\bigcirc)$ , IR from this paper (solid line), and optical  $^{9,13}(\bigcirc)$ . The radio and optical data have been convolved with the 6 arc s beam used for the IR measurements. The error bars refer to the IR data and are due mainly to uncertainties in subtracting the stellar background in M87. At the flux peak, the errors at all frequencies are  $\sim 3\%$  and remain constant with D (distance from the nucleus) in the radio but increase towards the nucleus in the optical and IR. Beyond 20 arc s a flux of 38 mJy per beam has been subtracted from the radio points to eliminate the contribution from the extended ridge seen at 15 GHz (ref. 5). The letters refer to locations of the various knots  $^8$ .

(5) The optical and near-IR emission dominate the observed energy losses from the jet. At a distance of 15.7 Mpc (ref. 14), the luminosity of knot A alone at V is  $1.6 \times 10^{41}$  erg s<sup>-1</sup> from a region less than 25 pc across<sup>8</sup>. The electrons responsible for this radiation have  $\gamma \sim 10^6$  if we assume the equipartition value for the magnetic field strength  $(H \sim 10^{-3}~G)^{-15}$ .

In classical synchrotron theory <sup>16</sup> a high frequency spectral break may be due to either (1) a break in the electron energy distribution or (2) energy dependent losses.

In regions of low radiation flux as in extended radio sources, synchrotron emission dominates high frequency energy loses. For an isotropic particle distribution and a continuous injection of electrons the expected break is  $\Delta \alpha = 0.5$ . A similar break is expected in regions of high radiation flux where Compton scattering dominates the energy losses. A more dramatic break is possible if either: (1) the particle pitch angle distribution is highly ansotropic or (2) the injection of electrons ceased a time t yr ago where:

$$t^2 = 4 \times 10^8 (H \sin \theta)^{-3} \nu_b^{-1} \tag{1}$$

where H is the magnetic field strength in G;  $\theta$  the particle pitch angle; and  $\nu_b$  the frequency of the spectral break.

The cessation of particle injection is an attractive hypothesis because the expected  $\Delta\alpha$  matches the observations:  $\alpha_{low} = (\gamma - 1)/2 = 0.6$  to  $\alpha_{high} = (2\gamma + 1)/3 = 1.8$  (ref. 16). However, the time since cessation is extremely short compared with the light travel time between the knots or from the nucleus to the knots. For example, given an equipartition magnetic field strength of  $H \ge 10^{-3}$  G,  $t \le 30$  yr (ref. 15). The nearly identical value that we find for the break frequencies in the four brightest knots requires that the time since last particle injection into each knot is identical to within 40% of the light travel time from the nucleus to knot A, assuming a magnetic field of  $10^{-4.5}$  G. For larger fields this restriction is, of course, much worse. Therefore, an additional difficulty for the synchroton loss model for the

spectral break is that no matter how the energy is supplied (for example, electrons or protons streaming from the nucleus or in situ acceleration), and given reasonable magnetic field values  $(H \le 10^{-4.5} \, \text{G})$ , the 'shut off' time for energy input is identical from knot-to-knot to less than the light travel time from knot-to-knot. Only a favourable projection angle can save this mechanism for consideration, a possibility that could be tested by further observations of the jet in the range 4,000–8,000 Å.

The expected spectral break is also steeper in the case of a highly anisotropic particle pitch angle distribution (or distribution in H sin  $\theta$  to be more precise). For electrons at a single pitch angle an exponential cutoff is observed at high frequencies even for continuous particle injection. This is consistent with the optical and UV observations11 which approximate a very steep power law between 1,000 and 5,000Å but could exponentially decay in the unobservable EUV. However, if the observed X-ray point is an extension of the optical-UV power law, the spread in pitch angle (assuming a constant magnetic field strength) must be at least an order of magnitude in  $\sin \theta$  with more electrons populating the larger pitch angles and thus responsible for the observed optical radiation. Either of these two situations is possible if particles streaming at low pitch angles (and thus with long synchrotron lifetimes) are pitchangle-scattered when they reach the observed knots. However, the great similarity among the high frequency spectral indices of the individual knots means that the scattering process must be so uniform in knots separated by thousands of light years that the particle distributions in  $H \sin \theta$  are virtually identical from knot to knot. Perhaps knot-to-knot variations do exist in the spectra above the break but the present observations are not accurate enough to reveal them.

Based on the above, we favour interpreting the shape of the spectrum of the jet as being due to the underlying electron energy distribution. If this is true it is probably then that the X-ray flux arises from Compton scattering. Otherwise, to avoid an additional high frequency spectral break, the radiating particles should show negligible synchrotron losses even for the  $\gamma \sim 10^7$  electrons responsible for the X rays. The very short synchrotron loss time scale for these electrons (1-200 yr for  $H = 10^{-3} - 10^{-4.5}$  G) limits the size of the emitting region. An equipartition field strength of  $H \ge 10^{-3} \,\mathrm{G}$  would require that each knot be smaller than 4 m arc s. The expected Comptonscattered X-ray flux would then exceed the observed flux by about an order of magnitude<sup>17</sup>. This discrepancy can be reduced but not entirely removed by assuming a much smaller magnetic field, or by requiring the acceleration to take place along a line or in a very thin slab as might be expected with a shock front acceleration model. Thus, the X-ray radiation can be of synchrotron origin only if anisotropies in the radiation field and the electron velocity distribution reduce the Compton scattering substantially.

The inverse Compton origin of the X-ray radiation can be tested by observing the overall jet spectrum in the Einstein band. A second frequency observation would be expected to detect the difference between the expected slopes for a synchrotron ( $\alpha = 1.7$ ) and inverse Compton ( $\alpha \le 0.8$ ) origin for the X rays. The inverse Compton X-ray slope is expected to be the same as the observed low frequency synchrotron slope ( $\nu \le 10^{14}$ ).

If the photon spectrum does reflect the underlying electron particle distribution, there are two possibilities for the origin of these electrons:

First, in situ acceleration overcomes the difficulties due to synchrotron losses described above but whatever acceleration process is responsible for the high energy electrons, it must be remarkably uniform in sites separated by thousands of light years in M87. As in the particle pitch angle scattering model for the high frequency break, the expectation for in situ acceleration models is that the different knots will have different spectra reflecting variations in acceleration parameters (for example, magnetic field strength and length scale over which the acceleration process takes place).

leste per transmission groups of the contraction of

The large characteristic  $\gamma$  s of  $10^6$  in the jet also pose a problem for statistical acceleration mechanisms involving magnetic fields. Typically  $\gamma \sim H^2 dr/c$  for these types of processes (for example, Fermi or betatron acceleration where  $H^2/c$ is the magnetic field energy and dr is the length scale over which it is applied). Thus, for an equipartition field and knot sizes between 2 and 20 pc, the expected  $\gamma$  s are only  $10^{2-3}$ . However, large ys are expected for processes whereby electrons gain energy due to motion through an electric field such as could be produced at a shock front moving through a region containing a magnetic field<sup>18</sup>. For this class of models  $\gamma \sim qH \, dr/c$  (q is the electron charge) and thus gives characteristic  $\gamma$ s of  $10^{6-7}$  for the above parameters. This electric field acceleration model is also much less sensitive to variations in source size as  $\gamma(r) \propto r^{-1}$ instead of  $r^{-3}$  for the magnetic acceleration models. However, in either case knot-to-knot variations would still be expected and have not yet clearly been seen.

Second, an external source of particle energy is possible if a proton beam is emanating from the nucleus1. This removes the problem of synchrotron losses and naturally explains the identical spectra of all the knots. Such a proton beam produces electrons by p-p collisions and subsequent muon decay into energetic electrons and  $\gamma$  rays. Using the formalism of Gould and Burbidge<sup>19</sup>, Felten<sup>1</sup>, derives the relationship between the  $\gamma$ -ray flux  $\phi(>E)$  (photons cm<sup>-2</sup> s<sup>-1</sup>) above an energy E (eV) and the observed synchrotron spectrum  $F(\nu_e)$  in W m<sup>-2</sup> Hz<sup>-1</sup> with slope s where  $\nu_e = 10^{-6}$  HE<sup>2</sup>:

$$\phi(>E) = 7 \times 10^{8} [a(2s+1)]^{-1} (0.2)^{s} HEF(\nu_{e})$$
 (2)

where H is the magnetic field in G and a(s) is a function of spectral index s (see ref. 20, p. 68). As the dominant energy electrons occur at the break frequency  $\log \nu_e = 14.75$ , for an equipartition field of  $H = 10^{-3}$  G the  $\gamma$ -ray energies associated with break frequency photons are  $E = 8 \times 10^{11}$  eV. These are  $\gamma$ s in the range to which Cerenkov light detectors are sensitive. Equation (2) predicts  $\gamma$ -ray fluxes of  $10^{-11}$  photons cm<sup>-2</sup> s<sup>-1</sup>, an order of magnitude less than the present upper limit on the  $\gamma$ -ray flux from M87 above 10<sup>11</sup> eV (ref. 21).

If we assume that the magnetic field strength is the equipartition value, then there is a relationship between the observed

angular size of the knots and the  $\gamma$ -ray for the M87 jet in the proton beam model:

$$\phi(>10^{11} \text{ eV}) \approx 1 \times 10^{19} \theta^{-6/7} \text{ d} \exp(-28.8 + 0.55 \log \theta)$$
 (3)

where  $\theta$  is the angular size in m arc s. Unfortunately equation (3) predicts only an order of magnitude increase in  $\phi$  between  $\theta = 300$  and 1 m arc s. The  $\gamma$ -ray flux decreases almost as fast as the magnetic field strength decreases away from equipartition; therefore, the proton beam mechanism is easily consistent with present observation.

We conclude that there are four observations which will constrain theoretical models of the M87 jet even more than the present observations:

- (1) Flux measurements for each knot in the jet between 4,000 and 8,000 Å to determine more accurately the high frequency spectral index and break frequency for the knots. These observations are crucial in determining whether an in situ process (acceleration or pitch angle scattering) is operating in the jet. These observations require a two-dimensional linear detector to subtract the contribution from the galaxy, which is quite strong at these wavelengths.
- (2) Speckle interferometry and VLBI observations of the knots to determine more accurately the angular size of the knots and thus the equipartition magnetic field strength and inverse Compton fluxes. The optical size is crucial because of longer synchrotron lifetimes, the knot sizes may be larger in the radio than in the optical because of particle diffusion away from the acceleration region.
- (3) Improved  $\gamma$ -ray observations at high energies, to constrain the proton beam model.
- (4) A second frequency X-ray observation at HRI resolution (≤3 arc s) to determine the X-ray spectral index and thus whether the X-ray radiation is due to a high energy tail of the optical synchrotron emission or to inverse Compton scattering from lower energy ( $\nu \le 10^{14} \text{ Hz}$ ) photons.

We thank B. Binkert for help at the 2.25-m telescope, Ethan Schreier and Eric Feigelson for communicating X-ray results before publication, and John Scott and John Cocke for helpful discussions. This research was supported by the NSF and NASA.

# Sm-Nd age of Kambalda and Kanowna greenstones and heterogeneity in the Archaean mantle

M. T. McCulloch & W. Compston

Research School of Earth Sciences, Australian National University, Canberra, ACT 2600, Australia

A precise Sm-Nd age of 2,790  $\pm$  30 Myr and an initial ratio corresponding to  $\varepsilon_{Nd} = +3.4 \pm 0.6$  has been determined for the Kambalda sequence from the eastern Yilgarn Block of Western Australia. The high initial 143Nd/144Nd implies a long-lived light rare-earth element-depleted (high Sm/Nd) source for the Kambalda volcanics and therefore provides definitive evidence for ancient heterogeneities in the Archaean mantle.

THE Sm-Nd isotopic systematics have been examined in maficultramafic and felsic volcanics at Kambalda and Kanowna in the Yilgarn Block of Western Australia. This study aims (1) to determine the original ages of the volcanic complexes, which have been difficult to establish by other methods, and (2) to determine their initial <sup>143</sup>Nd/<sup>144</sup>Nd as a means of further understanding the evolutionary history of the crust and mantle. The Kambalda and Kanowna volcanics are typical of the greenstone belts which occur within the gneissic and granitic rocks of the Eastern Goldfields Province and have similarities with Archaean greenstones from other cratons. For example, the common occurrence of spinifex-textured Mg-rich basalts and peridotites of komatiitic affinity are analogous to those found in the Barberton area of southern Africa and Munro Township, Canada<sup>1-4</sup>.

Despite intensive isotopic studies, the original ages of extrusion for the greenstones in this part of the East Yilgarn Block remain equivocal. Rb-Sr and Pb-Pb age determinations<sup>5-8</sup> register specific events within the range ~2,760-2,400 Myr. However, because of the extensive metamorphic and metasomatic history of the terrain, even the oldest of these is interpreted as a minimum for the original igneous ages. Recent applications of the Sm-Nd method to dating of greenstones from other Archaean terrains<sup>9-12</sup> have shown rare earth elements (REE) are much less mobile during metamorphism, so that the Sm-Nd system may be more conclusive for the definition of original ages. Due to the lack of preservation of primary mineralogy, the present study is based on whole rock analyses.

Volcanics have been analysed from two localities (see Fig. 1), Kambalda which is composed mainly of mafic and ultramafic extrusives and Kanowna where felsic volcanism predominates. Tentative stratigraphic correlations <sup>13,14</sup> suggest that Kanowna is older, being part of a first volcanic cycle while Kambalda is thought to be at the base of a second volcanic cycle.

† Measured on spiked samples; normalized to  $^{144}$ Nd/ $^{142}$ Nd = 0 636151. The value for BCR-1 determined in this laboratory is 0 51184 ± 2.

The Kambalda volcanics form a conformable succession consisting of an ultramafic unit some 240-600 m thick sandwiched between two basaltic sequences15. The lower basalt (the 'footwall basalt') is dominantly a massive metatholeiite with pillowed and flow-top breecia horizons and has many geochemical affinities with modern-day oceanic tholeiites4. The upper 'hanging wall' basalt is more heterogeneous and contains a lower variolitic-textured section separated by a sulphide rich sedimentary horizon from an upper massive fine-grained metatholeiite. The Mg-rich ultramafic sequence consists of a large number of flow units many of which have spinifex textures. Major nickel sulphide deposits occur at the base of the ultramafic sequence. Intruding the mafic-ultramafic sequence is a series of felsic intrusives of which a large portion consists of a 'sodic-granite' 15. It has been suggested that these intrusives are recrystallized porphyries representing the subvolcanic expression of felsic volcanism within the mafic-ultramafic succession. The Kanowna area consists of a major felsic volcanic complex which overlies a sequence of metabasalts and ultramafics13. The metabasalts consist of a sequence of pillowed, amygdaloidal basaltic flows within which occurs several metaperidotites. These rocks are thought to be the stratigraphically lowest unit in the Kalgoorlie area. The overlying felsic volcanics consist of lapilli tuffs, pyroclastic flows, agglomerates and a conglomerate containing felsic and ultramafic clasts in a predominately felsic volcanogenic matrix. Intruding this sequence is an altered quartz-rich porphyry. Gold has been produced from a quartz reef in the conglomerate.

#### Results

The procedures used for the isotopic analyses of Sm and Nd are described elsewhere <sup>17</sup>. In this study, samples were totally spiked and dissolved using HF, HClO<sub>4</sub> and HCl. Measurements were made of Nd<sup>+</sup> using triple filaments. The total Nd blank is 100 pg and is therefore negligible for our study. The  $\varepsilon_{\rm Nd}$  values are defined as:

$$\varepsilon_{Nd} = \left[ \frac{\binom{143}{Nd} \binom{144}{144} Nd)_{maxt}^{T}}{\binom{143}{Nd} \binom{144}{144} Nd)_{CHUR}^{T}} - 1 \right] \times 10^{4}$$

where  $(^{143}\text{Nd})^{144}\text{Nd})^{T}_{\text{CHUR}} = (^{143}\text{Nd})^{144}\text{Nd})^{0}_{\text{CHUR}} - (^{147}\text{Sm})^{144}\text{Nd})^{0}_{\text{CHUR}} = (^{147}\text{Sm})^{144}\text{Nd})^{0}_{\text{CHUR}} = (^{147}\text{Sm})^{144}\text{Nd})^{0}_{\text{CHUR}} = (^{147}\text{Sm})^{144}\text{Nd})^{144}_{\text{CHUR}} = 0.511836$  and  $(^{147}\text{Sm})^{144}\text{Nd})^{0}_{\text{CHUR}} = 0.1967$ ;  $\lambda_{\text{Sca}} = 6.54 \times 10^{-12} \text{ yr}^{-1}$ .  $(^{143}\text{Nd})^{144}\text{Nd})^{144}_{\text{min}}$  is the measured ratio in the rock, corrected for decay since the time of

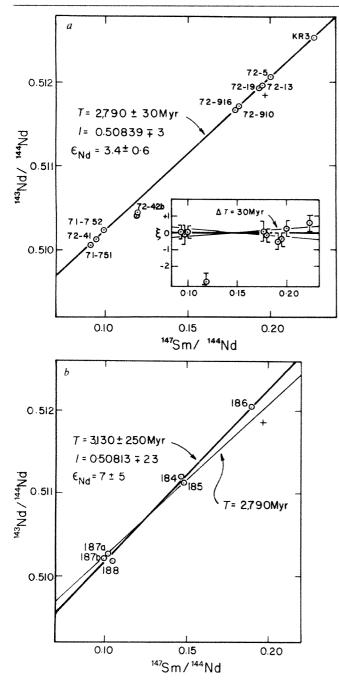

Fig. 2 a, Sm-Nd evolution diagram for the Kambalda volcanic sequence. The precise age and initial  $^{143}$ Nd/ $^{144}$ Nd result from combining the basalts and ultramafics with an associated sodic granite and felsic porphyry. A less precise age of  $2.910\pm170$  Myr is obtained from the footwall, hanging wall and ultramafics volcanics alone. +, The present-day chondritic value  $^{26}$ . b, Sm-Nd evolution diagram for the Kanowna volcanics. The large deviations from a best fit line do not allow a precise age determination.

crystallization T. The  $^{147}$ Sm/ $^{144}$ Nd enrichment factor relative to 'CHUR' is given by

$$f^{\text{Sm/Nd}} = \left[ \frac{(^{147}\text{Sm}/^{144}\text{Nd})_{\text{meas.}}}{(^{147}\text{Sm}/^{144}\text{Nd})_{\text{CHUR}}^0} - 1 \right]$$

The results of the isotopic measurements are listed in Table 1 and shown in Fig. 2a, b. Figure 2a shows the whole rock results from Kambalda. The footwall, hanging wall and ultramafic sequences from Kambalda have a relatively restricted range in Sm/Nd of  $\sim \pm 10\%$  and approximately chondritic relative abundances of REE (Fig. 3). In contrast, the sodic-granite and associated porphyries have pronounced light rare-earth element (LREE) enrichments (low Sm/Nd). Combining all the

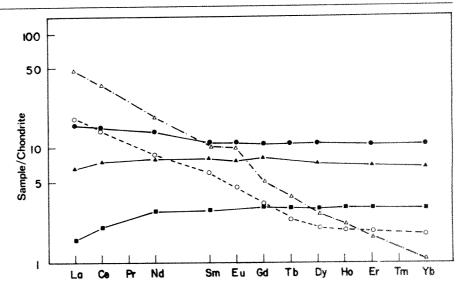

Kambalda samples yields a large range of Sm/Nd and therefore a large range in  $^{143}\text{Nd}/^{144}\text{Nd}$  of 48  $\epsilon_{\,\text{Nd}}^{\,0}$  units. As shown inset in Fig. 2a, all the data points apart from an altered ultramafic lie on the best fit line within analytical uncertainty, and define an age of  $2,790 \pm 30$  Myr  $(2\sigma)$ , an initial  $^{143}$ Nd/ $^{144}$ Nd =  $0.50839 \pm 3$   $(2\sigma)$ . If it is assumed that the sodic-granite and felsic porphyry are isochronous with and have the same initial <sup>143</sup>Nd/<sup>144</sup>Nd as the footwall, hanging wall and ultramafic volcanics, then the Sm-Nd age may represent the time of crystallization of this complex. This joint age is the same within errors as previous Pb-Pb (ref. 8) age determination for the sodic-granite of  $2.760 \pm 70$  Myr. The strict co-linearity of the felsic and ultramafic data supports this contention. A less precise age of 2,910 ± 170 Myr is obtained from the footwall, hanging wall and ultramafic volcanics alone. The lower precision of  $\pm 170$  Myr is due to their smaller range in Sm/Nd. An ultramatic from the alteration zone at the felsic porphyry-ultramafic contact is the only discrepant sample. One explanation is that the Sm-Nd isotopic system in this sample has been disturbed by contamination with non-radiogenic Nd during a late alteration process associated with the emplacement of the felsic porphyry. The unusual LREE enrichment and abundances in the ultramafic (Fig. 3) is consistent with this interpretation. Alternatively the age obtained by combining the footwall, hanging wall and ultramafic volcanics with the altered ultramafic  $(3,100 \pm 100 \text{ Myr})$  could be registering a time of early alteration. However, this is unlikely due to the similarity between the LREE enrichments observed in the altered ultramafic and the younger felsic porphyry. The initial  $^{143}$ Nd/ $^{144}$ Nd obtained from the  $2,790\pm30$  Myr isochron lies above the CHUR evolution curve ( $\varepsilon_{Nd} = 3.4 \pm 0.6$ ).

Figure 2b shows the results from Kanowna. The samples show similar variation of Sm/Nd with bulk composition, the ultramafic having the highest Sm/Nd, metabasalts and intermediate Sm/Nd and the felsic samples the lowest Sm/Nd. Despite a range in  $^{143}$ Nd/ $^{144}$ Nd of 36  $\varepsilon_{\rm Nd}^0$  units, the Kanowna samples produce a very imprecise age of  $3,130 \pm 250$  Myr and initial  $^{143}$ Nd/ $^{144}$ Nd of  $0.50813 \pm 23$  ( $\varepsilon_{Nd} = 7 \pm 5$ ). For comparison, the Kambalda isochron is also shown in Fig. 2b. The large deviations from the best fit line of the Kanowna data are in distinct contrast with the Kambalda data and could be due to significant differences in age, initial <sup>143</sup>Nd/<sup>144</sup>Nd or redistribution of Sm and Nd during later metamorphisms. In contrast to the Kambalda samples which are from deep drill-cores, the Kanowna samples are from the surface outcrops so we cannot exclude the possibility that their Sm-Nd isotopic system has been disturbed by recent weathering. As far as can be ascertained, there is no obvious difference in the extent of modification of equivalent rock types at Kanowna and Kambalda. For example, metabasalts from Kanowna and Kambalda have similar major element chemical contents (for example K<sub>2</sub>O < 0.1%) and ocelli bearing samples have been analysed<sup>7</sup> from both localities (80–184 and 72–910, 72–916). Although disturbance of the Sm-Nd system by later metamorphic and metasomatic events cannot be discounted (for example, sample 72-42b) the consequences of age and initial <sup>143</sup>Nd/<sup>144</sup>Nd variations will now be considered.

#### Sm-Nd whole rock isochrons

The evolution of initial <sup>143</sup>Nd/<sup>144</sup>Nd with time in terrestrial rocks of varying ages has been shown <sup>9-12,18,24-26</sup> to approximate the evolution expected in a reservoir having a fixed, chondritic Sm/Nd. For this reason, rocks which are closed systems and derived from the reference mantle reservoir (CHUR) will produce isochrons that pivot about the present-day values of Sm/Nd and <sup>143</sup>Nd/<sup>144</sup>Nd in CHUR. This is shown in Fig. 4 for isochrons of age 1,000, 2,000 and 3,000 Myr. For example, a suite of rocks derived from a chondritic reservoir 3,000 Myr ago will today produce a linear array with the <sup>143</sup>Nd/<sup>144</sup>Nd being proportional to Sm/Nd. A sample that has the same Sm/Nd as in the chondritic reservoir will continue to evolve in a manner identical to the reference reservoir. This applies to rocks of all ages and thus the present-day values of Sm/Nd and <sup>143</sup>Nd/<sup>144</sup>Nd

Fig. 3 Chondrite normalized REE abundance patterns for the Kambalda volcanics<sup>27,33</sup>, sodic-granite<sup>28</sup> and altered ultramafic. The unusual LREE enrichment of the altered ultramafic may be due to contamination by LREE from the younger sodic-granite. △, Na-granite; ♠, hanging wall basalt; ○, altered ultramafic; ♠, footwall basalt; ■, ultramafic.

in CHUR will be a fixed point common to all isochrons derived from CHUR. Thus samples with Sm/Nd approximately the same as in CHUR ( $f^{\text{Sm/Nd}} \approx 0$ ) will not provide meaningful age information. Samples which are most sensitive to age variations are those with non-chondritic Sm/Nd ( $f^{\text{Sm/Nd}} \neq 0$ ). These systematics have important implications for this study (and others) as it has been necessary to combine felsic volcanics ( $f^{\text{Sm/Nd}} \sim -0.5$ ) with mafic and ultramafic volcanics ( $f^{\text{Sm/Nd}} \sim 0$ ) to obtain an adequate range in Sm/Nd for precise dating. At Kambalda the sodic granite and felsic porphyry (the low Sm/Nd end-members) intrude the mafic-ultramafic sequence and therefore the  $2.790\pm30$  Myr 'isochron' represents only a minimum age for the mafic-ultramafic volcanics. It is possible, within the analytical uncertainties, that a significant age difference of  $120\pm200$  Myr may exist between the mafic-ultramafic volcanics and felsic intrusives.

The disparate Kanowna data clearly imply disturbance of the Sm/Nd isotopic system or age and initial <sup>143</sup>Nd/<sup>144</sup>Nd variations. For example, the large deviations between the low Sm/Nd felsic rocks requires that the felsic porphyry 187 has either a higher initial <sup>143</sup>Nd/<sup>144</sup>Nd or is younger than the dacite 188. The geological field relationships are consistent with the latter explanation. The basalts 184 and 185 are spatially closely related suggesting that their deviations are more probably due to variable initial <sup>143</sup>Nd/<sup>144</sup>Nd. The contrast between the Kambalda and Kanowna data may be due to dominance of felsic volcanism at Kanowna. Felsic volcanics are chemically more evolved, implying isotopically more evolved and heterogeneous mantle or crustal sources.

The Sm-Nd model age  $^{18,19}$   $(T_{CHUR}^{Nd})$  is the time in the past when the major REE fractionation in a rock occurred during its derivation from the model mantle reservoir CHUR. In Figs 2 and 4 this is equivalent to the age defined by the line joining the sample with the present day values of 143Nd/144Nd and Sm/Nd in the chondritic reservoir CHUR. Thus only fractionated (nonchondritic Sm/Nd) samples define precise model ages. The T<sub>CHUR</sub> model ages from the low Sm/Nd Kambalda felsic volcanics, 2,510-2,540 Myr, are the same within analytical uncertainty whereas the Kanowna felsic volcanics have a range in  $T_{CHUR}^{Nd}$  of 2,490-2,690 Myr. All these model ages are significantly younger than the ages indicated by the whole-rock isochrons. This discrepancy is due to the higher initial <sup>143</sup>Nd/<sup>144</sup>Nd of the whole-rock isochrons compared with that in CHUR. This can be seen in Fig. 2a, b where the best fit lines to the mafic-ultramafic samples have a higher <sup>143</sup>Nd/<sup>144</sup>Nd relative to CHUR for a chondritic Sm/Nd. The higher initial  $^{143}$ Nd/ $^{144}$ Nd relative to CHUR (corresponding to  $\varepsilon_{Nd} = 3.4 \pm$ 0.6 for Kambalda and  $\varepsilon_{Nd} = 7 \pm 5$  for Kanowna) is essentially independent of age for the mafic-ultramafic samples. The possible explanations for the well defined Kambalda point are discussed below.

#### Heterogeneous Archaean mantle

The well-defined initial 143Nd/144Nd of the Kambalda volcanics corresponding to  $\varepsilon_{Nd} = 3.4 \pm 0.6$  provides some of the first definitive evidence for ancient long-lived heterogeneities in the Archaean mantle. This can be seen in Fig. 5a where the initial <sup>143</sup>Nd/<sup>144</sup>Nd determined on Archaean igneous rocks are summarized on a graph of  $\epsilon_{Nd}$  versus time. Most of the previously determined 2,600-2,800 Myr data points cluster near the  $\varepsilon_{Nd}(T) = 0$  line suggesting that the Archaean mantle was relatively undifferentiated and the Sm/Nd of the Earth was uniform (within about  $\pm 3\%$ ) and close to the average chondritic value used to calculate the CHUR curve26. The Kambalda point (solid) lies distinctly above the CHUR curve and unambiguously implies a mantle source with  $f^{\text{Sm/Nd}} > 0$  for time scales > 100Myr. Its position above the CHUR curve is significant as the interpretation of data which lies below the CHUR curve is complicated by the possibility that the magmas may be contaminated with pre-existing continental crustal rocks with negative  $\varepsilon_{Nd}(T)$  values. This is exemplified by the Stillwater point<sup>20</sup>. Evidence for the derivation of magmas from positive  $\varepsilon_{Nd}$  mantle has been presented for Archaean gneisses from eastern India by Basu et al.31 and for Proterozoic rocks by DePaolo34

The Sm/Nd enrichment factor  $(f^{\text{Sm/Nd}})$  of the Kambalda magma source can be calculated as a function of the time (Ts)

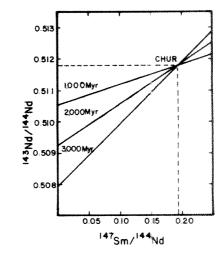

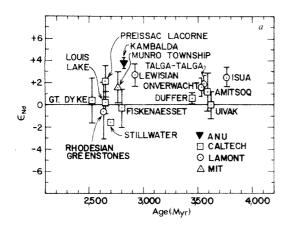

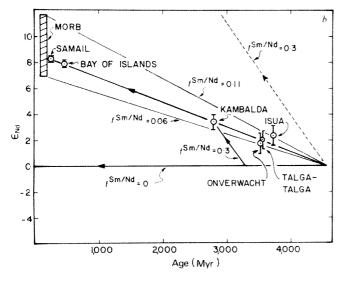

Fig. 4 Sm-Nd evolution diagram for isochrons of age 1,000, 2,000 and 3,000 Myr. Due to the approximate chondritic Sm/Nd evolution of the mantle 9-12,18,24-26, mantle-derived samples with Sm/Nd approximately the same as chondrites (CHUR) do not alone provide age information.

that it became fractionated relative to CHUR by using the relationship 18:

$$\varepsilon_{\rm Nd}(T) = f^{\rm Sm/Nd}Q_{\rm Nd}(Ts-T)$$

For Ts equal to the age of the Earth (Ts = 4,550 Myr, T = 2,790 Myr,  $Q_{Nd} = 0.0251 \text{ Myr}^{-1}$ ),  $f^{\text{Sm/Nd}} = 0.08$ . This is a minimum value and implies a mantle source with a time average Sm/Nd from 4,550 Myr to 2,790 Myr that was 8% higher than CHUR. This evolution curve is shown in Fig. 5b together with the initial <sup>143</sup>Nd/<sup>144</sup>Nd of Kambalda and the older mafic-ultramafic sequences, Talga-Talga<sup>32</sup>, Onverwacht<sup>11</sup> and Isua<sup>10</sup>. The colinearity of these data suggest the possible existence of an ancient (>4,000 Myr) ultramafic mantle source with f0.08. This reservoir would today have  $\varepsilon_{Nd} \sim +9$  and could thus be the source of the positive  $\varepsilon_{Nd}$  oceanic basalts. This is contrary to previous suggestions<sup>29,30</sup> of a younger (1,800-2,000 Myr) source for modern day oceanic basalts. To distinguish between these evolutionary models it is apparent that additional high precision initial <sup>143</sup>Nd/<sup>144</sup>Nd are required from Precambrian oceanic basalts of different ages.

**Fig. 5** a, Fractional deviations in parts per  $10^4$  of initial  $^{143}$ Nd/ $^{144}$ Nd of Archaean rocks $^{9-12,18-20,23-26,32}$ , from evolution in the CHUR reservoir  $^{18}$ . The  $\varepsilon_{\rm Nd}$  value of  $+3.4\pm0.6$  for the Kambalda sequence implies derivation from a long-lived LREE depleted (high Sm/Nd) source. b, Possible evolution of <sup>143</sup>Nd/<sup>144</sup>Nd based on the initial <sup>143</sup>Nd/<sup>144</sup>Nd of Kambalda, Isua<sup>10</sup>, Onverwacht<sup>11</sup> and Talga–Talga<sup>32</sup>. The single evolution curves with f<sup>Sm/Nd</sup> of from 0.06 to 0.10 can account for the initial <sup>143</sup>Nd/<sup>144</sup>Nd of these samples as well as present day oceanic basalts. An alternate explanation for the high initial <sup>143</sup>Nd/<sup>144</sup>Nd of the Kambalda sequence involves multi-stage evolutions with  $f^{\text{Sm/Nd}} \leq 0$ . For comparison initial  $^{143}\text{Nd}/^{144}\text{Nd}$  and inferred evolution of some highly fractionated ( $f^{\text{Sm/Nd}} \simeq 0.3$ ) Apollo 12 and 17 lunar maria basalt sources  $^{21,22}$  are also shown (dashed line).

An ancient (>4,000 Myr) high f<sup>Sm/Nd</sup> mantle source would imply an early differentiation of the Earth as well as incomplete mantle mixing to allow the preservation of these distinctive magma reservoirs. We note that this hypothesis is independent of the exact CHUR evolution curve for the bulk Earth but may be influenced by possible interlaboratory biases between the Kambalda and Onverwacht, Talga-Talga, Isua data. The initial <sup>143</sup>Nd/<sup>144</sup>Nd of the Apollo 12 and 17 lunar maria basalts <sup>21,22</sup> is also consistent with an early differentiation (~4,500 Myr) of planetary bodies resulting in the formation of even more highly fractionated magma reservoirs having  $f^{\text{Sm/Nd}} = 0.3$ .

An alternative interpretation of the Kambalda initial ratio is that the time of differentiation of the source is substantially younger than 4,500 Myr. This would require a more strongly LREE depleted source. For example, for  $T_s = 3250 \text{ Myr}$ ,  $f^{\text{Sm/Nd}} = 0.3$ , which by analogy with the lunar data, is probably a maximum  $f^{\text{Sm/Nd}}$  value.

#### **Conclusions**

The Sm-Nd whole rock systems have been examined in two volcanic sequences from the eastern Yilgarn Block of Western Australia. The predominantly mafic-ultramafic sequence at Kambalda has preserved uniform and regular Sm-Nd systems consistent with a well defined crystallization age of  $2,790 \pm 30$ Myr and an initial  $^{143}$ Nd/ $^{144}$ Nd = 0.50839 ± 3. In contrast, data from the felsic Kanowna complex are highly dispersed with a poorly defined age of  $3{,}130 \pm 250$  Myr and initial  $^{143}$ Nd/ $^{144}$ Nd =  $0.50813 \pm 23$ . The differences between the two sequences are poorly understood but may reflect disturbance of the Sm-Nd system or large variations in the age and initial ratios of the Kanowna complex. Due to the deviant Kanowna data array, the age difference between Kanowna and Kambalda is not considered to be significant although it is consistent with inferred stratigraphic correlations 13,14

Although the whole rock samples from Kambalda form a perfect linear array (apart from an altered ultramafic) the age and initial <sup>143</sup>Nd/<sup>144</sup>Nd is constrained by combining maficultramafic volcanics with felsic volcanics. Consequently any age differences which may exist between felsic and mafic volcanics are not readily apparent. For example, a plausible hypothesis for the formation of the Kambalda complex may be the extrusion of the mafic-ultramafic volcanics in an ocean basin at  $2,910 \pm 170$ Myr (age given by the mafic and ultramafic volcanics only). Then, within  $120 \pm 200$  Myr (that is at 2,790 Myr) the sodic granite and related felsic intrusives were produced by partial melting of an eclogite source. An eclogite or more specificially a garnet bearing source<sup>28</sup> is implied by their pronounced LREE enrichments ( $f^{\text{Sm/Nd}} \ll 0$ ) and may be the subducted equivalents of the mafic and ultramafic volcanics now preserved in the Kambalda complex.

Regardless of the question of the original age, the initial <sup>143</sup>Nd/<sup>144</sup>Nd of the Kambalda sequence is significantly greater than the chondritic evolution curve with an  $\varepsilon_{Nd}$  value of  $\pm 3.4 \pm$ 0.6. For the sodic-granite alone, the  $\varepsilon_{Nd}$  value is independently set at +3.9, if the Pb-Pb<sup>8</sup> age of 2,760 Myr is used. The high initial <sup>143</sup>Nd/<sup>144</sup>Nd requires an earlier LREE depleted (high Sm/Nd) source for the Kambalda volcanics and therefore provides some of the first definitive evidence for long-lived heterogeneites in the Archaean mantle.

We thank M. Perfit, O. A. Bavington and S. R. Taylor for REE analyses of the Kambalda ultramafics and hanging-wall basalt. J. J. Gresham, G. Loftus-Hills and J. C. Roddick provided the Kambalda samples and helped interpret the geology. We thank J. Barreda for typing the manuscript.

# Structure of vitamin D-dependent calciumbinding protein from bovine intestine

D. M. E. Szebenyi, S. K. Obendorf & K. Moffat

Section of Biochemistry, Molecular and Cell Biology, Clark Hall, Cornell University, Ithaca, New York 14853, USA

The structure of vitamin D-dependent calcium-binding protein from bovine intestine, determined crystallographically to 2.3 Å, contains a pair of calcium-binding domains similar to those in parvalbumin, but one domain has a longer and rearranged calcium-binding loop. This result has implications for structure predictions of other calcium-binding proteins such as calmodulin and S-100.

THE role of calcium as a 'second messenger' in the regulation of intracellular processes is now well established.1,2, and requires that intracellular calcium concentrations be precisely controlled. A wide variety of calcium-binding proteins, with affinity constants<sup>3</sup> in the range 10<sup>-8</sup>-10<sup>-5</sup> M, have been identified which either participate in this control or exhibit activities modulated by calcium (ref. 4 and refs therein). One such class of proteins comprises the vitamin D-dependent calcium-binding proteins, which have been studied in various species. In birds, a protein of molecular weight (MW) of ~28,000 is found in the intestine, kidney, brain, shell gland and other organs. In mammals, a protein of similar size is found in various tissues, but the predominant intestinal calcium-binding protein is a smaller, 10,000-MW species<sup>5</sup>. The chicken protein has four high-affinity calcium-binding sites  $(K_D \sim 10^{-6} \text{ M})$  and the bovine intestinal protein two such sites<sup>5,6</sup>. The intestinal calcium-binding proteins are soluble species, located in the cytoplasm of the absorptive cells<sup>7</sup>. Their synthesis requires the presence of  $1\alpha$ , 25-dihydroxyvitamin D<sub>3</sub> (1,25(OH)<sub>2</sub>D<sub>3</sub>) which, when given to a rachitic rat, produces an immediate increase in intestinal absorption of calcium, followed after a delay of several hours by the production of calcium-binding protein8. The protein thus cannot be involved in the initial translocation of calcium across the gut wall but could play a part in later stages of calcium metabolism. Alternatively, it could act as an intracellular calcium buffer, as the calcium-sensitive component of a transport molecule or as some other calcium-controlled regulator of absorptive cell

Although the three-dimensional structures of several calcium-binding proteins have been determined, of these only carp parvalbumin is believed to be involved in the regulation of intracellular calcium3. Parvalbumin contains two 29-amino acid calcium-binding domains, each consisting of a loop of 12 residues flanked by two  $\alpha$ -helices approximately at right angles to each other  $^{10,11}$ . This helix-loop-helix conformation is termed  $^{11}$ an 'EF hand' (see Fig. 1 of ref. 12 for derivation of the name). Based on an analysis of the key structural features of the two EF hands in parvalbumin, Tufty and Kretsinger<sup>12</sup> identified 16 amino acids in the 29-residue sequence that they believed were essential to the formation of a calcium-binding EF hand. They applied this 16-residue test sequence to a wide range of protein

sequences, and predicted that EF hands would be found in troponin C and other muscle proteins<sup>12</sup>. Subsequently this prediction was generalized to: intracellular calcium-modulated proteins contain EF hands and conversely, any protein which contains an EF hand is calcium modulated<sup>3,13,14</sup>.

This hypothesis has attracted broad interest but has not been subjected to a structural test. We present here the three-dimensional structure of a vitamin D-dependent calcium-binding protein from bovine intestine (ICaBP), which from its amino acid sequence6 is predicted to contain one, and possibly two, EF hand(s) (see Fig. 1). This protein indeed contains two helixloop-helix calcium-binding domains, resembling the EF hands in parvalbumin in both internal conformation and relationship to one another, but differing from them in detail.

#### X-ray analysis

ICaBP (minor A form; see Fig. 1) was purified115 from bovine intestinal mucosa to electrophoretic homogeneity and crystallized at pH 8.7-8.9 (ref. 16, Table 1). Derivatives for multiple isomorphous replacement phasing were prepared by soaking crystals in solutions containing various heavy-atom reagents and X-ray data were collected using both screened precession films and a Syntex P21 diffractometer, as summarized in Table 1. The single site in the Nd3+ derivative was located by a difference Patterson synthesis; sites in subsequent derivatives were determined by a combination of difference Patterson and crossphased difference Fourier syntheses<sup>17</sup>. Heavy-atom refinement was carried out using a program based on the ideas of Blow and Crick<sup>18</sup>, and of Matthews<sup>19</sup>. Statistics for the final cycle of refinement are shown in Table 1.

The native electron density map calculated at 2.3-A resolution using the multiple isomorphous replacement phases shows most of the molecular boundary and the general course of the polypeptide chain but appears noisy. To increase the signal-tonoise ratio, we applied a density modification procedure based on those of Schevitz et al.<sup>20</sup> and of Agard and Stroud<sup>21</sup>. This approach imposes two constraints: non-negativity of the electron density and uniformity (at a low level) of the electron density in solvent regions. Although only 35% of the unit cell is solvent, compared with 82% in the tRNA crystals used elsewhere20, this proved a useful approach. Density modification

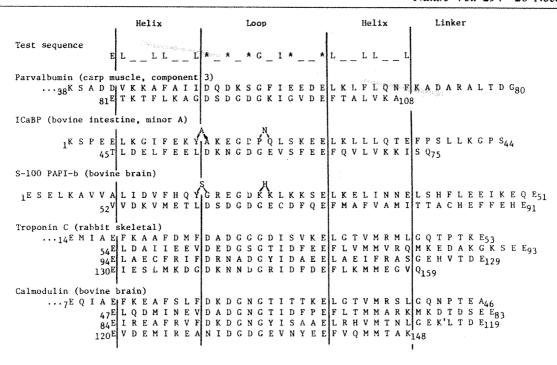

Fig. 1 Sequences of some calcium-binding proteins, with EF hand test sequence. The test sequence represents residues suggested from earlier studies to be critical to the EF hand structure<sup>12</sup>. In the test sequence, \* indicates an oxygen-containing residue (D, E, N, Q, S, T), L indicates a hydrophobic residue (L, V, I, F, M), I indicates a hydrophobic residue with isoleucine preferred, G is glycine, and an underscore indicates that any amino acid may appear in that position. Insertions and deletions have been postulated to maximize homology between sequences. N-terminal portions of parvalbumin<sup>34</sup>, troponin C<sup>35</sup> and calmodulin<sup>36</sup> have been omitted. The 'major' (native) form of ICaBP has the sequences Ac-Ser-Ala-Lys-minor A. Amino acid code: A, alanine; C, cysteine; D, aspartic acid; E, glutamic acid; F, phenylalanine; G, glycine; H, histidine; I, isoleucine; K, lysine; K', trimethyllysine; L, leucine; M, methionine; N, asparagine; P, proline; Q, glutamine; R, arginine; S, serine; T, threonine; V, valine; W, tryptophan; Y, tyrosine. S-100 PAPI-b (bovine brain) sequence was from ref. 37; that of ICaBP, ref. 6.

$$\begin{split} R_c &= \frac{\Sigma \|F_{p \text{H}_{obs}}\| - \|F_{p \text{H}_{obs}}\|}{\Sigma \|F_p\| - \|F_{p \text{H}_{obs}}\|}, \text{ summed over centric reflections} \\ R_K &= \frac{\Sigma \|F_{p \text{H}_{obs}}\| - \|F_{p \text{H}_{obs}}\|}{\Sigma \|F_{p \text{H}_{obs}}\|}, \text{ summed over all reflections} \end{split}$$

Native crystals were grown from 65-80% saturated  $(NH_4)_2SO_4$  in 0.02 M Tris pH8.7-8.9, and stored in 90% saturated  $(NH_4)_2SO_4$ . Heavy-atom solutions contained the appropriate reagent in 90% saturated  $(NH_4)_2SO_4$ . The crystals are space group  $P2_12_12$ ; unit cell dimensions are:  $a=56.2\pm0.1$ ,  $b=42.6\pm0.1$ ,  $c=29.2\pm0.1$  Å. There is one molecule per asymmetric unit and a solvent content of 35%. Films were scanned on an Optronics P200 rotating drum densitometer and scaled together using the CORRELATE program of G. N. Reeke's ROCKS computing package. Diffractometer data were scaled to the film data; to compensate for absorption effects, different scale factors were permitted for different ranges of the diffractometer setting angles  $\phi$  and  $\chi$ . Intensities were placed approximately on an absolute scale using a Wilson plot. Derivative scale factors were adjusted to eliminate peaks and holes at heavy-atom sites on a native electron density map. Anomalous dispersion data for all derivatives were used in phasing.  $Nd^{3+}$  and  $Au(CN)_2^-$  positions and occupancies were refined phasing on all three derivatives but holding  $Nd^{3+}$  and  $Au(CN)_2^-$  parameters fixed. Effective isotropic temperature factors (Bs) were set to values of 10–15 and not refined.

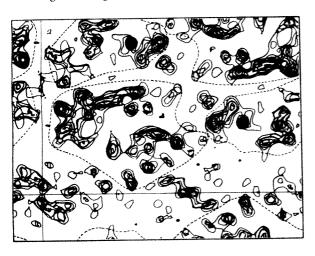

A.D. residual = 
$$\left[\frac{\sum w(AD_{obs} - AD_{calc})^2}{\sum wAD_{calc}}\right]^{-1/2}$$

<sup>\*</sup> Very weak native reflections and those with less than two good derivative measurements (counting the two members of a KAu(CN)<sub>2</sub> anomalous pair as two derivatives) were not used in phasing. Only the 2,080 reflections between 9.09 and 2.33 Å resolution were used for heavy-atom refinement, but all 2,157 reflections were used to phase the native map.

<sup>†</sup> Net occupancy. Nd<sup>3+</sup> replaces Ca<sup>2+</sup> (18 electrons), so the total Nd<sup>3+</sup> occupancy would be  $\sim$ 37 electrons.

increased the figure of merit from 0.61 to 0.79 and improved the clarity of the electron density map (compare the representative electron density sections before modification [Fig. 2a] with those after [Fig. 2b]). One or two spurious breaks in the polypeptide chain were introduced, but in most regions the modified map proved easier to interpret.

A Kendrew-Watson molecular model of ICaBP was constructed from the modified map using a Richards optical comparator<sup>22</sup>. The polypeptide backbone is shown in Fig. 3, based on the  $\alpha$ -carbon positions measured from this model. In most places, the course of the main chain is clear, although the exact conformation in some of the non-helical regions remains to be confirmed by crystallographic refinement. The register of the amino acid sequence<sup>6</sup> with the map is firmly established by the placement of the four prolines, all of which appear as flattened regions of high electron density in the main chain, and

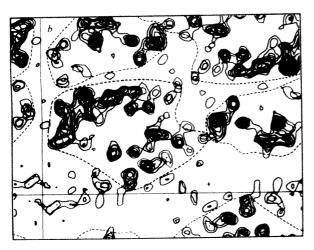

Fig. 2 Section through ICaBP electron density, from z = 0.375 to z = 0.425, before (a) and after (b) density modification. The density modification procedure was as follows: a probable molecular envelope was determined by inspection of the initial map, and all electron density values outside the envelope were considered to be in solvent regions and were set to a small constant value. Within the envelope, negative values were multiplied by 0.1 (to flatten out holes without creating sharp edges) and peaks above a certain maximum (slightly higher than the largest value on the original map) were truncated to that maximum. To reduce artefacts due to sharp edges, each point just outside the molecular envelope or just within the rim of a truncated peak was set to the average of itself with the 26 surrounding points. Inverse Fourier transformation of the modified map produced a new set of structure factors, whose phases were combined with the original phases using the method of Bricogne<sup>38</sup>. The combined phases were used with the observed amplitudes to produce a new map. After four cycles, the envelope was adjusted as indicated by the resulting map and applied to the original map. Seven cycles were then carried out using the revised envelope (indicated by dotted lines).

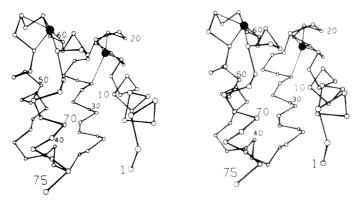

Fig. 3 Stereo view of the ICaBP  $\alpha$ -carbon backbone, with the two bound calcium ions.  $\bigcirc$ ,  $\alpha$ -carbons;  $\blacksquare$ , calcium ions.

by very clearly defined density for all aromatic side chains. The density is not consistent with an earlier sequence<sup>23</sup>.

### Overall structure of ICaBP

ICaBP is a globular protein of approximate dimensions  $25 \times$  $30\!\times\!30\,\mbox{\normalfont\AA}.$  It consists of four helices, designated I–IV and comprising residues 2-14, 24-35, 46-54 and 63-75, respectively, wrapped around the usual hydrophobic core of a soluble protein. There are hydrophobic contacts between side chains from all pairs of helices, and between the II-III linker and helices II and III. In addition to the four main helices, residues 36-41 are approximately helical, with hydrogen bonds formed between 36-40 and 38-41. Even neglecting this region, the helix content is ~63%, higher than indicated by circular dichroism studies (40±5% for bovine ICaBP (M. Jibson, unpublished results); 30% for the closely homologous porcine protein<sup>24</sup>). Regions I, II and III are standard  $\alpha$ -helices whereas IV begins with four residues of  $3_{10}$  helix and then becomes  $\alpha$ -helical. The region between helices III and IV is a calcium-binding loop of the EF hand type. Between I and II is a slightly longer loop which also binds calcium and may be described as a variant EF hand (see below). If the linker region between II and III is neglected, there is an approximate 2-fold axis relating the I-II and III-IV domains, illustrated by the view down this axis shown in Fig. 4a.

The single tyrosine, Tyr 13, lies on the surface of the molecule, making a probable hydrogen bond to Glu 35, thus tying helices I and II together. Birdsall *et al.*<sup>25</sup> proposed, on the basis of NMR work, that the Tyr lies in a hydrophobic pocket involving one Ile and two Phe. We find Tyr 13 to be in a very shallow depression formed by Ile 9, Leu 30, Leu 31, Thr 34 and Glu 35. Phe 10, Phe 36 and Phe 66 are within 11 Å of the Tyr, which is close enough for some interaction. Fluorescence measurements demonstrate complete resonance energy transfer from all five Phe residues to the Tyr. For the two Phe further than 10–12 Å from the Tyr, energy transfer presumably involves an inter-Phe relay system; no Phe is more than 11 Å from the rest.

#### EF hands in ICaBP

The calcium-binding loop between helices III and IV is extremely similar to the EF hand prototype found in parvalbumin. The calcium is coordinated by side-chain oxygens from Asp 54, Asn 56, Asp 58 and Glu 65 and by the main-chain carbonyl from Glu 60. Both carboxyl oxygens of Glu 65 are ligands, so that there are six protein oxygens surrounding the calcium ion at distances (unrefined) of 2.2–2.6 Å. The calcium in the EF loop of parvalbumin has a water molecule in its coordination sphere; the ICaBP III–IV calcium is clearly exposed to solvent, and initial refinement suggests that a solvent molecule is a seventh ligand. Helices III and IV are at an angle of 121° with a minimum inter-axis distance of 8.06 Å, compared with 102° and 7.63 Å in the parvalbumin EF hand. Fitting the α-carbons of the ICaBP III–IV domain to those of the parvalbumin EF region

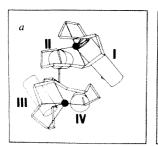

Table 2	ICaRP.	compared with parvalbumin

a, Angles and minimum inter-axial distances between all pairs of helices which are in contact. The inter-helix angle is calculated by considering the helix axes as vectors, and is  $0-90^{\circ}$  for parallel,  $90-180^{\circ}$  for antiparallel helices. The distance is the minimum distance between infinite lines along the helix axes; the closest approach of the finite helices may be greater. b, Agreement between  $\alpha$ -carbon positions of indicated segments after rotation and translation of one set of coordinates so as to minimize  $\Sigma d_i^2$ , where  $d_i$  is the distance between the ith  $\alpha$ -carbons of the two segments after rotation and translation. Parvalbumin coordinates were supplied by the Protein Data Bank<sup>33</sup>.

results in an average (r.m.s.) discrepancy of 2.40 Å for the entire domain and 1.26 Å for the calcium-binding loops alone; the corresponding values for CD as opposed to EF are 1.86 and 0.93 Å (Table 2).

However, the I-II loop (two residues longer) is rather different. The insertion of Ala 14 means that the first predicted calcium ligand, Ala 15, is on the outside rather than the inside of helix I, and of course the alanine side chain contains no oxygen. This lack is accommodated by using the main-chain carbonyl of Ala 15 as a ligand. The loop is further rearranged about the second and third calcium ligands, Glu 17 and Asp 19, so that they also coordinate Ca<sup>2+</sup> with their main-chain carbonyls rather than their side chains. Following the second insertion of Asn 21 (or Pro 20), the loop adopts essentially the normal EF hand conformation. The main-chain carbonyl of Glu 22 and the two carboxyl oxygens of Glu 27 constitute the remaining calcium ligands, giving a total of six protein oxygen ligands. Ca-O distances (unrefined) are 2.2-2.6 Å. Due to the different conformation of the N-terminal portion of the loop, the I-II calcium

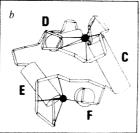

Fig. 4 α-Carbon backbone and calcium ions viewed down the approximate intramolecular 2-fold axis of (a) ICaBP and (b) parvalbumin, residues 38-108. Helices are represented by cylinders and other polypeptide chains as a folded ribbon. ●, Calcium ions.

is much less accessible to solvent than the III-IV calcium, and it is unlikely that a solvent molecule is a seventh ligand.

The stretches of calcium-binding loop from residues 22-25 and 60-63 run antiparallel to one another and are joined by a hydrogen bond between Leu 23 and Val 61, across the approximate 2-fold axis, resembling a small piece of  $\beta$ -sheet. This arrangement also occurs in parvalbumin, between the CD and EF loops. The calcium ions are separated by 11.9 Å in parvalbumin and by 12.5 Å in ICaBP.

In both the conformation of the two calcium-binding domains and their disposition with respect to each other, ICaBP thus resembles the C-terminal two-thirds of parvalbumin (Fig. 4). If the II-III linker and the two inserted residues in the I-II loop are omitted, a fit of the remaining 61 ICaBP  $\alpha$ -carbons to the corresponding parvalbumin  $\alpha$ -carbons gives a r.m.s. discrepancy of 3.07 Å. Compare, for example, the 5.7 Å r.m.s. discrepancy between 60-residue segments of T4 lysozyme and hen egg-white lysozyme, and the 0.9 Å (for a 40-residue stretch) to 1.5 Å (for 80 residues) discrepancy between myoglobin and haemoglobin  $\beta$ -chain<sup>27</sup>.

Despite this resemblance, there are significant differences between the conformations of ICaBP and parvalbumin. Helices II and IV in ICaBP are in contact, whereas the corresponding helices D and F in parvalbumin are not (Table 2). Inter-helix angles differ and are generally more regular in ICaBP (Table 2). Parvalbumin has an extended D-E linker, a bend in the D helix and a straight F helix, whereas the ICaBP II-III linker is highly folded, helix II is straight and there is a bend in helix IV. These differences in helix spacing and linker folding are only to be expected, because if ICaBP were to adopt the parvalbumin conformation, it would have a large hole in its 'underside' which is filled by the A and B helices in parvalbumin. ICaBP helix III is shorter than parvalbumin helix E and IV is slightly longer than F. Finally, the I-II and CD loops differ: the latter is a normal EF hand calcium-binding loop whereas the former is a variant. Thus, although ICaBP exhibits the same overall helix-loophelix structure found in parvalbumin, the disposition of the

<sup>\*</sup>The transformation relating these segments, expressed as a screw operation, is 172°, -0.78 Å for parvalbumin, and 168°, -0.32 Å for ICaBP, that is, in both cases the two segments are related by an approximate 2-fold axis.

<sup>†</sup> Asn 21 omitted. Ala 14 used in 14 residue loop but omitted from helix-loop-helix comparison.

helices with respect to each other, both within one domain and between domains, is clearly different. This may hinder attempts to search for EF hands by application of molecular replacement techniques to crystals of other calcium-regulated proteins such as calmodulin and troponin C.

#### Calcium-binding to ICaBP

We believe that the structure described here represents ICaBP having both high-affinity sites fully loaded with calcium and no significant occupancy of low-affinity calcium sites. Weakly bound calcium was removed by dialysis against distilled water. The presence of calcium in the high-affinity sites is evidenced by peaks near both sites on a native anomalous difference Fourier (the two highest peaks on the map); and, in I-II, by the presence of a peak at the calcium position on the native electron density map. Site III-IV does not have a peak at exactly the calcium position, but as it is a heavy-atom site (for the Nd<sup>5+</sup> derivative), distortions in this region are to be expected. Full occupancy of the high-affinity sites is suggested by the good definition of the polypeptide chain in both calcium-binding loops and by the absence of changes in structure amplitudes on soaking crystals in 10 mM CaCl<sub>2</sub>. NMR<sup>25</sup> and trypsin digestion<sup>28</sup> experiments reveal a substantial conformational change in the protein on removal of one or both calcium ions. This conformational change is unfortunately sufficient to disintegrate ICaBP crystals soaked in 1.0 mM EDTA, and attempts to grow crystals in the absence of calcium have been unsuccessful. Thus, the conformational changes which occur on release of one or two calcium ions are unknown; they might involve only small rearrangements of the calcium-binding loops, or motion of the flanking helices with respect to each other, or motion of the two calcium-binding domains.

The two calcium-binding sites differ in their calcium affinities, indicated by the removal in EDTA (solution of 1:1 EDTA/ICaBP) of only one calcium (C. S. Fullmer, personal communication). The relative affinities for Tb<sup>3+</sup>, a fluorescent model for Ca<sup>2+</sup>, also differ, by at least a factor of 20 (ref. 26). It is apparent from the X-ray structure that the III-IV site is more exposed to solvent than the I-II site; this agrees with the observation that, in a crystal soaked for 2 days in 1.0 mM NdCl<sub>3</sub>, Nd<sup>3+</sup> displaces the III-IV but not the I-II Ca<sup>2+</sup>. We suggest that the I-II site may be a structural site, saturated with calcium in all physiological conditions, whereas the III-IV site is a regulatory site which binds or releases calcium as intracellular calcium levels vary.

#### Implications for the structure of other calcium-binding proteins

ICaBP is a member of the calmodulin family of calcium-binding proteins, for which it is proposed that an ancestral four-domain calcium-binding protein was produced by successive gene duplications<sup>29</sup>. Calmodulin and troponin C have retained this type of structure, and bind four calcium ions per protein molecule. Some other members of the family have lost the calciumbinding ability of one or more of the domains. In parvalbumin, the first domain was deleted entirely and the second, the AB domain, no longer binds calcium; in ICaBP, two domains were deleted and the N-terminal I-II domain was modified by the insertion of two residues, while retaining its calcium-binding

The S-100 PAPI-a and PAPI-b proteins belong to the same branch of the calmodulin family as ICaBP; divergence seems to have occurred after the modification of the I-II loop (Fig. 1 shows the PAPI-b sequence; PAPI-a is 58% homologous to PAPI-b overall and almost identical with respect to the calciumbinding loops<sup>30</sup>). The S-100 proteins are thus expected to contain one variant and one normal EF hand, arranged similarly to those in ICaBP.

The calcium-binding characteristics of PAPI-b, however, are more complex than those of ICaBP. Two Ca<sup>2+</sup> are bound (per monomer) at pH 8.3 but only one at pH 7.6. Furthermore, the

presence of K+ inhibits binding of calcium to the high-affinity sites31. PAPI-b contains three basic side chains Lys-His-Lys in positions corresponding to Pro-Asn-Gln in the I-II loop of ICaBP (Fig. 1). It is likely that titration of the histidine is responsible for the pH dependence of calcium-binding, and the overall affinity of this site for cations may be lowered relative to ICaBP by the proximity of additional basic side chains.

Kretsinger and Barry<sup>32</sup> constructed a model for the fourdomain calcium-binding protein, troponin C, from four EF hands, by first pairing two hands as in the parvalbumin CD plus EF region, duplicating the pair and placing the non-calciumbinding ends of the pairs together so that a quasi 2-fold axis perpendicular to the one within each pair relates the two pairs. The molecule then exhibits quasi-222 symmetry. A similar model may be constructed for other four-domain proteins such as calmodulin. This structural prediction is supported by our results: the conformation of the ICaBP III-IV domain proves that the normal EF hand occurs other than in parvalbumin, and the stability of pairs of EF hands is demonstrated by the maintenance of such a pair, related by an approximate 2-fold axis, in ICaBP even when one calcium-binding loop has been appreciably modified.

The overall conformations of proteins in the calmodulin family are thus determined by the preferred formation of EF hands and pairs of hands, which may be packed together into higher aggregates. Differences in function are made possible by variation in the conformation of the calcium-binding loops, in the disposition of helices with respect to each other, and/or by differences in the linker regions. The conformation of the linkers, in particular, is quite free to evolve as required for interaction with other molecules, without disturbing the overall shape or calcium-binding abilities of the protein.

This determination of the ICaBP structure provides the first structural confirmation of the EF hand hypothesis, and also expands the definition of an EF hand, first to include structures whose helices are disposed rather differently from those in parvalbumin (for example, the ICaBP III-IV domain), and second to include structures with a modified calcium-binding loop such as the ICaBP I-II domain. These latter variant EF hands are not necessarily detectable from sequence comparisons; if the existence of two insertions is not recognized, only 8 out of 16 residues of the I-II domain match the EF hand test sequence. Hence the recognition of such variants in other proteins (except for those such as the S-100 proteins which are clearly closely related to ICaBP) will require the determination of their three-dimensional structures.

We thank R. H. Wasserman and C. S. Fullmer for providing us with our initial samples of ICaBP, for assistance in protein preparation, and for the ICaBP sequence before its publication; J. Clardy made diffractometer time available, and B. W. Siegel contributed the use of his Optronics film densitometer. We received computer programs from various sources, notably G. N. Reeke, L. Ten Eyck, R. C. Ladner, G. Petsko and the CRYSNET facility at Brookhaven. A. J. S. Jones improved the ICaBP purification scheme and performed the solution studies of ICaBP fluorescence and Tb3+/Ca2+ binding. J. Wenban provided assistance in the preparation of figures and in much of the experimental work. This research was supported by NIH grant AM 21453. K. M. holds a NIH Career Development Award, AM 00322.

### Absorption of $\gamma$ rays in active galaxies as a test of the jet hypothesis

#### L. Bassani & A. J. Dean

Department of Physics, University of Southampton, Southampton SO9 5NH, UK

Powerful X-ray emission is a common feature of active galaxies, some of which have also been detected as  $\gamma$ -ray sources<sup>1-5</sup>. The observed high luminosities, coupled with reports of variability on time scales of days or less at X-ray energies<sup>6</sup> and of 1 yr or less at  $\gamma$ -ray energies<sup>3</sup>, suggest that both emissions may originate in the same volume deep within the nucleus of the galaxy. Under this assumption we investigate here the attenuation of  $\gamma$  rays as a result of pair-production in photon-photon collisions with X rays and show that whilst Seyfert galaxies are transparent to  $\gamma$ radiation up to ~1 GeV, QSOs and BL Lac objects are generally opaque about 1 MeV. However, the detection of  $\gamma$  rays from these latter classes of objects may be explained if beaming of the  $X-\gamma$  emission is assumed.

The relevance of photon-photon absorption to specific astronomical sources has been discussed by several authors<sup>7</sup> Following their formalism, a photon of energy  $E_x$  may collide with a photon of energy  $E_{\gamma}$  and produce an electron-positron pair provided that

$$E_{\mathbf{X}}E_{\mathbf{y}} \ge \frac{2(mc^2)^2}{(1-\cos\theta)}\tag{1}$$

where  $mc^2 = 0.511 \text{ MeV}$  is the rest mass energy of the electron and  $\theta$  the angle between the directions of motion of the two photons. For fixed values of  $E_{\gamma}$ , the pair production crosssection  $\sigma(E_X)$  rises steeply from zero at the threshold energy  $E_X = E_s$  to a maximum value  $\sigma_{\text{max}} = 1.7 \times 10^{-25} \text{ cm}^2$  at  $E_X = 2E_s$ and then falls off as  $E_x^{-2}$  for energies  $E_x \gg E_s$ . The optical depth for this process can be written as:

$$\tau = R \int \sigma(E_{\mathbf{X}}) N_{\mathbf{X}}(E_{\mathbf{X}}) \, \mathrm{d}E_{\mathbf{X}} \tag{2}$$

where the cross-section  $\sigma$  and the density of X-ray photons per unit energy  $N_x$ , are assumed to be constant throughout the source region of size R. In the first instance we consider the case of isotropic emission and for simplicity set  $\theta = \pi/2$ . Furthermore within the limits of accuracy required by this calculation it is sufficient to approximate  $\sigma(E_x)$  by a rectangular function of height  $\sigma_{\text{max}}$  and width 2.5  $E_{\text{s}}$ . Consequently, the optical depth may be written as

$$\tau = R\sigma_{\text{max}}N_{\text{X}}(2E_{\text{s}})2.5E_{\text{s}} \tag{3}$$

To estimate  $N_X$  we use the X-ray luminosity and write

$$N_{\rm X}(2E_{\rm s}) = f(\alpha)L_{\rm X}\frac{(2E_{\rm s})^{-\alpha}}{4\pi R^2 c}$$
 (4)

where  $\alpha$  is the source photon spectral index at X-ray energies.

For  $L_{\rm X}$  taken over a fixed energy band (generally 2-10 keV),  $f(\alpha)$  is a slowly varying function of  $\alpha$ . Introduction of numerical values in equation (3) leads to the final expression

$$\tau = 2.5 \times 10^{-28} f(\alpha) \frac{L_{\rm X}}{R} (2E_{\rm s})^{-\alpha+1}$$
 (5)

with  $L_X$  in erg s<sup>-1</sup>, R in cm, and  $E_s$  in keV. For convenience we have taken  $\alpha = 1.6$  for each of the sources considered. This value represents a reasonable description of the observed spectra of Seyfert galaxies<sup>11</sup> and quasars<sup>12</sup>. It is less precise for BL Lac objects, whose spectral variability makes the choice of an average  $\alpha$  value difficult<sup>13</sup>. However, the function  $f(\alpha = 1.6)$ only varies between 0.34 and 0.37 for the different energy bands over which the X-ray luminosities are calculated. Table 1 lists the values of  $L_X$  and  $R = c \Delta t$  together with the optical depths  $\tau$ for a range of  $\gamma$ -ray energies. Note that R represents an upper limit on the size of the X-ray region and consequently a lower limit on  $\tau$ , because, in many cases, the  $\Delta t$  values are related to periods between observations rather than to measured changes in the X-ray emission.

Table 1 shows that Seyfert galaxies are transparent to their  $\gamma$ radiation up to energies of ~1 GeV. The size of the emitting region is probably not very different from one Seyfert to another so that the value of  $\tau$  will ultimately depend on the X-ray luminosity of the object in question. Consequently, the less bright X-ray sources could be the best candidates for γ-ray emission. As Type II Seyferts have an average X-ray luminosity which is approximately two orders of magnitude lower than that of type I Seyferts 14,15 we suggest that Type II objects should be primary targets for future y-ray observations. In contrast it is clear that quasars and BL Lac objects must be effectively opaque to y rays of a few MeV or more, if isotropic emission of both the X and  $\gamma$  rays is assumed. Many of the electron-positron pairs produced in this absorption process will eventually annihilate to produce 511 keV radiation, which is no longer absorbed by the X-ray photon field and can probably escape depending on the matter density present close to the emission region. If the positrons are slowed down such that the line is not smeared out by the relativistic kinematics, we may expect that these objects should be characterized by a weak 511 keV flux. Because in the case of the QSO 3C273 γ rays have been detected<sup>5</sup> in the energy range 50-500 MeV, we must conclude that either the X- and  $\gamma$ -ray emission regions do not coincide or that anisotropic, highly collimated radiation is a characteristic of this active galactic nucleus. The degree of continuity in the spectral emission between the hard X-ray and the low energy  $\gamma$ -ray fluxes suggests that the possibility of beamed radiation is more likely. In the simplified model of jets consisting of streams of relativistic particles, equation (1) shows that as  $\theta$  approaches zero, the threshold energy,  $E_s$ , tends towards infinity and the absorption process of y rays becomes inhibited for higher and higher energies. For the case of a homogenous diverging beam with opening angle  $\theta_0$ , the limiting photon energy which is absorbed

by photon-photon pair production can be written as  $E_{\gamma} \sim$  $\sqrt{2} mc^2 (1-\cos\theta_0)^{-\frac{1}{2}}$ . Thus to observe  $\gamma$  rays from 3C273 would require a beaming angle of few degrees or less. More realistic jet models 16-20 involving relativistically moving plasmas, present a more complex picture. First the absorption calculation must be made in the rest frame of the flow where the emission is isotropic. Second, corrections must be applied for the combined relativistic effects of Doppler blueshifting of the  $\gamma$ -ray photons and of beaming which is responsible for increasing the source luminosity. The overall effect is to reduce the absorption of  $\gamma$ 

rays in emitters of beamed radiation.

It has been suggested 19,20 that the sequence of extragalactic objects, radio-quiet quasars, radio-loud quasars and blazars (optically violent variable quasars and BL Lac objects) correspond to sources associated with relativistic jets, which are received at progressively smaller angles to their axes. In this picture, the nucleus may be considered to have an isotropic steady and unpolarized continuum which in the optical range is responsible for the emission lines and, in addition, a variable, strongly polarized source associated with a jet and beamed in a cone of small solid angle. The beamed component progressively dominates the isotropic emission as the angle between the observer and the jet axis decreases. Under this hypothesis, BL Lac objects probably represent the extreme case of alignment with the beam, so that the isotropic component and, consequently, the emission lines are completely swamped. Of the three quasars discussed here, two are classified as radio loud quasars<sup>21</sup> and probably represent a less extreme case of alignment with the direction of the Earth. We would therefore expect both classes of objects to be  $\gamma$ -ray sources as along the beam direction little photon-photon absorption is expected. Conversely sources for which the beam is not directed towards the observer would not be detected as  $\gamma$ -ray emitters. If this is true, a future γ-ray survey of extragalactic objects should be carried out to test the possible correlation between the  $\gamma$ -ray spectral intensity and the angle of observation with respect to the jet axis. We conclude that y-ray observations of extragalactic objects could not only test the beaming hypotheses but also support the argument that the classification of 'different' types of active galaxies is related to their orientation with respect to the Earth, rather than any intrinsic differences in their internal structure.

### Are coronal loops stable?

#### I. J. D. Craig & A. N. McClymont

Department of Mathematics, University of Waikato, Private Bag, Hamilton, New Zealand

The solar corona is now recognized as a highly inhomogeneous plasma that comprises a complex network of individual arch and loop-like structures1. This has led to the recent idea that the isolated 'coronal loop' may form a basic building block of quiescent solar and stellar atmospheres2.3. Theoretical , however, suggest that isolated loops are violently studies4.5 unstable and hence should collapse on the radiative time scale of the plasma. The simple fact that loops exist stably over long periods demonstrates the inadequacy of the current theory. We point out here that a crucial ingredient is missing from the theory and hence reconcile the existence of coronal loops with the disruptive effect of the radiative instability.

The central assumption in theoretical loop modelling is that dynamic effects can be neglected in the local energy balance<sup>6</sup>.

<sup>† 10%</sup> X-ray variability also observed on  $\Delta T = 610^3$  s (ref. 23).

 $<sup>\</sup>ddagger L_X$  in the range 0.5-4.5 keV

<sup>§</sup> Redshift measurement doubtful.

 $<sup>||</sup>L_X|$  in the range 0.2-3.5 keV.

Baity, W. A. et al. Astrophys. J. 244, 429-435 (1981).
 Perotti, F. et al. Nature 282, 484-486 (1979).

<sup>3.</sup> Perotti, F. et al. Astrophys. J. 247, L63-L66 (1981).

Hence it is postulated that an unknown heating mechanism supports the loop against energy losses by radiation and energy redistribution by heat conduction along the confining magnetic field lines. This leads quite naturally to a scaling law which, for the loop of length l, relates the plasma pressure P to the peak coronal temperature in the loop:

$$P = 2.1 \times 10^{-11} \beta^{1/2} T_0^{13/4} / l \text{ dyn cm}^{-2}$$
 (1)

where  $\beta$  is a number of the order of unity accounting for the shape of the heating function<sup>2</sup>. An important prediction of the quasi-static model therefore is that small, hot loops should be several orders of magnitude denser than larger, cooler structures. That such behaviour is confirmed observationally is very strong support for the quasi-static analysis.

Yet an astrophysical plasma hotter than 10<sup>5</sup> K may be unstable because the radiative loss rate decreases with increasing temperature. Field's stability criterion<sup>7</sup> for a uniform conducting plasma is

$$P < 6.1 \times 10^{-11} T^{13/4} / l \text{ dyn cm}^{-2}$$
 (2)

Although equation (2) is not strictly applicable to a non-uniform coronal loop, comparing equations (1) and (2) we anticipate that conduction may not be able to control the instability. Independent normal mode stability analyses in fact claim that the 'thermally isolated' loop (that is, a loop whose temperature gradient vanishes at the lower boundary) is radiatively unstable<sup>4,5</sup>. This result implies that if the loop is to exist at all it cannot be described by a quasi-static energy balance. Thus it has been speculated that a dynamic solution may exist in which the radiative instability drives periodic dynamic oscillations on the radiative time scale of the plasma4-6

This conclusion is disturbing for two main reasons: first, quiescent loops show little evidence of significant dynamical behaviour, nor are they observed to collapse on the radiative time scale of the plasma<sup>1-3</sup>. Second, detailed hydrodynamic models based on the same physics as the quasi-static analysis do not reveal oscillatory modes driven by the radiative  $instability^{8-10} \\$ 

In attempting to resolve this problem we have applied a standard normal mode analysis4 to a 'thermally isolated' loop (see also refs 5, 11). Two classes of lower boundary conditions are considered: in one case the base is held at a fixed chromospheric temperature  $(\delta T_b = 0)$ ; in the other the heat flux is assumed to vanish at the base  $(\delta F_b = 0)$ . As the former condition implies that the chromosphere can act as an infinite source or sink of heat while the latter implies that no heat is exchanged across the lower boundary9, we expect that a real loop must lie between these extremes. In either case, because the base of the loop cannot move freely  $^{12}$  ( $\delta v_{\rm b} = 0$ , where v is the velocity), the most unstable eigenmode is the first antisymmetric mode<sup>4</sup> symmetric modes tend to be stabilized by the rise in pressure which accompanies a temperature increase.

It can be proved that the loop is marginally stable in the case where the base temperature is held fixed. To see this, we note that the first antisymmetric eigenfunction given by

$$\delta T \propto T', \quad \delta v \propto T - T_{\rm b}$$
 (3)

where T' denotes the unperturbed temperature gradient, represents an analytic solution to the problem<sup>4</sup> corresponding to the case of zero growth. This result also establishes that the loop is unstable when  $\delta F_b = 0$ , as, by Sturm's oscillation theorem<sup>5</sup>, the eigenvalue λ (the negative of a normalized growth rate<sup>4</sup>) must decrease to satisfy the required boundary condition. However, the instability is physically insignificant if the amount of radiatively stable chromospheric material ( $T < 10^5$  K) at the foot of the transition region is sufficiently large. The growth time is then greater than any relevant time scale associated with the loop.

Figure 1 shows the first antisymmetric ( $\delta F_b = 0$ ) eigenvalue  $\lambda$ plotted against the ratio of chromospheric  $(T < 10^5 \text{ K})$  mass to coronal  $(T > 10^5 \text{ K})$  mass in the loop,  $N_{CH}/N_{CO}$ , for various base temperatures T<sub>b</sub>. A slight increase in chromospheric mass clearly produces a dramatic decrease in  $\lambda$ ; likewise the growth rate of the instability decreases. From the definition<sup>4</sup> of  $\lambda$  and

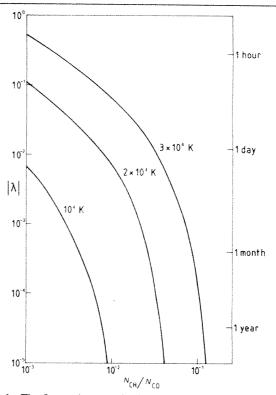

Fig. 1 The first antisymmetric eigenvalue  $\lambda$  (normalized growth rate) plotted against chromospheric mass  $(T < 10^5 \text{ K})$  for a range of base temperatures  $T_{\rm b}$ . The amount of chromospheric material  $N_{\rm CH}$ is expressed in units of the coronal mass  $N_{\rm CO}$ . On the right-hand scale actual growth times for the typical values  $T_0 = 2.5 \times 10^6 \text{ K}$  and  $l = 10^{9.5} \text{ cm}$  are shown.

the scaling law (1) we find (setting  $\beta = 1$ ) the actual growth time

$$\tau = 2.7 \times 10^{-5} \frac{l}{|\lambda| T_0^{1/4}}$$
 s (4)

which for the typical values  $T_0 = 2.5 \times 10^6 \text{ K}$  and  $l = 10^{9.5} \text{ cm}$ yields the growth times shown on Fig. 1. Values of  $\tau$  greater than a few weeks have no physical significance as the growth time exceeds the lifetime of a typical loop.

We conclude that the radiative instability is controlled essentially by the chromosphere: as more and more of the radiatively stable chromospheric plasma is included in the analysis the  $(\delta F_{\rm b} = 0)$  mode of instability tends towards the marginally stable case ( $\delta T_b = 0$ ). Very little chromospheric material is, in fact, required to counter the instability: between 1 and 10% of the coronal mass suffices. It follows that the rapid instabilities found previously<sup>4,5,11</sup> are simply a consequence of the neglect of the chromospheric influence.

Finally, we note that a complete solution to the problem requires the treatment of energy transport by radiative transfer in the chromosphere. Because only a minute fraction of the radiatively stable material available is required to quash the instability in the optically-thin approximation used above, we believe our conclusions will remain essentially unaltered by the inclusion of radiative transfer.

# Dayside electron cyclotron harmonic emissions

#### Kjell Rönnmark

Kiruna Geophysical Institute, University of Umeå, S-901 87 Umeå, Sweden

#### Peter J. Christiansen

Space and Plasma Physics Group, University of Sussex, Brighton BN1 9QH, UK

Observations of waves exhibiting an often complex frequency banding related to the electron gyrofrequency were first reported in 19701. Later observations2-5 showed that the spectral content of these electrostatic electron cyclotron harmonic waves is highly variable<sup>6,7</sup>, including single frequency emissions between the electron gyrofrequency  $\Omega_e$  and its first harmonic, multiple bands between consecutive harmonics of  $\Omega_e$ , and emissions in a single band far above the electron gyro-frequency<sup>8-10</sup>. These observations have led theorists to investigate both the linear instability which generates the waves 11-15 and various wave-particle 14,16 and wave-wave 17-18 interactions in which they may be involved. The consensus seems to be that at least two plasma components with different temperatures are required to destablilize electron cyclotron harmonic waves. We adopt this view here and test our present knowledge of electron cyclotron harmonic instabilities against the observed reality. To do this we use simultaneous observations of wave spectra and electron distribution functions, available in the GEOS 1 data from 25 August 1977 (see ref. 15). From these we present the wave event and then use the measured particle fluxes to derive a model distribution function, providing the input to a computer program which solves the plasma dispersion relation. From the computed temporal growth rates and group velocities, the total amplification of waves which are unstable within a limited volume of space is estimated.

The emissions observed by the \$300 wave experiment onboard GEOS 1 between 09.20 and 10.20 UT on 25 August 1977 are shown in Fig. 1. The spectrogram is derived from the large electric antenna 19 and consists of sets of 0-77 kHz sweeps of the stepped frequency analyser. The grey scaling is adjusted to the strongest signal in each sweep. The horizontal lines at 47.6 and 63.5 kHz are caused by the satellite clock pulses and are thus purely instrumental. The line  $f_{ce}$  indicates the electron gyrofrequency, which during the event was ~4.4 kHz. The variable high frequency emissions seen before 09.40 UT are known to be in the vicinity of the upper hybrid (or plasma) frequency. When the plasma frequency drops to around 30 kHz after 09.40 UT, signals appear between all gyroharmonics below the intensified plasma line. The signal at the second harmonic of the plasma frequency is believed to be (at least partly) instrumental, but it indicates a very strong signal at the fundamental. The emissions observed after 09.40 UT would belong to class 3 in the classification schemes of Gough et al.7 and of Hubbard and Birmingham<sup>6</sup>. The higher harmonics disappear at around 09.53 UT, while the  $3/2~\Omega_e$  emission persists until 10.00 UT. After this time, only the upper hybrid (or plasma) line remains. At 09.50 UT, the satellite was on the dayside (11.20 MLT) at  $L \sim 6.6$  and  $\sim 10^{\circ}$  magnetic latitude.

The importance of the cool plasma parameters for electron cyclotron harmonic instabilities is discussed in the accompanying paper by Horne *et al.*<sup>20</sup>. Low energy (0-500 eV) electron fluxes are measured by the S302 experiment onboard GEOS 1 (ref. 21), and information about the low energy electrons at 09.47 UT has been provided by J. Johnson, J. Sojka and G. Wrenn (personal communication). The main components have temperatures  $T_1 \approx 1 \text{ eV}$  and  $T_2 \approx 5 \text{ eV}$ , and the densities are

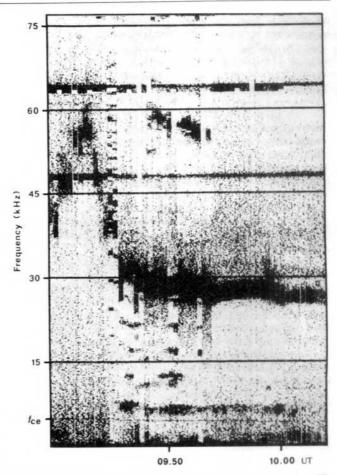

Fig. 1 Spectrogram emphasizing the wave event under study. The display begins at 09.20 UT the time scale is not uniform.

 $n_1 \approx 5.5 \times 10^6$  electron m<sup>-3</sup> and  $n_2 \approx 3.0 \times 10^6$  electron m<sup>-3</sup>. In addition, a component with temperature  $T_3 \approx 200$  eV and density  $5 \times 10^4$  electron m<sup>-3</sup> is observed. The flux of this component at a pitch angle of 80° is double the flux at 18°. This anisotropy and the slope of the energy spectrum match the low energy end of the distribution measured by the S310 experiment, although the flux values given by S310 are higher.

The particle experiment S310 provides pitch angle distributions and energy spectra in the range 0.35-22 keV (ref. 22). When the angle between the magnetic field and the spin axis is  $15^{\circ}-26^{\circ}$ , at least one of the four detectors with a narrow field of view ( $\pm 2^{\circ}$ ) passes through the loss-cone. In such cases even the very narrow loss-cone expected at geostationary altitudes can be resolved. At larger pitch angles, measurements are made by

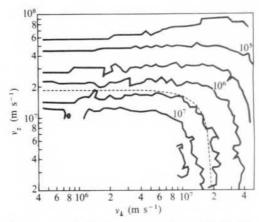

Fig. 2 The electron distribution function observed by S-310 at 09.45-09.48 UT. Phase space densities are given in units of electron cm<sup>-2</sup> s<sup>-1</sup> sr<sup>-1</sup> keV<sup>-1</sup>, and the dashed curve indicates 1 keV.

0028-0836/81/480335--04\$01.00

three other detectors. All seven detectors step through 32 energy steps, and a complete distribution function such as the one shown in Fig. 2 is obtained in  $\sim$ 3 min. As each detector is sampled 11.6 times per second, the distribution shown in Fig. 2 would ideally be based on  $\sim$ 15,000 samples, but as some data contaminated by sunlight and other effects must be rejected, the real number may be a few thousands lower. The pitch angle intervals scanned by different detectors normally overlap, and this overlap is used by an intercalibration routine to compensate for differences in the efficiency of the electron multipliers.

The contours of constant level plotted in Fig. 2 are derived by dividing the measured fluxes by the particle energy and transforming the energy and pitch angle of each sample to  $(v_{\perp}, v_z)$ -coordinates. The displayed part of velocity space is then covered by a network, consisting of  $43\times35$  meshes. Between each mesh point, the logarithm of a velocity component changes by 0.05. The average value of the distribution function is calculated within each mesh, and linear interpolation between nearest neighbours is used to define the function between the mesh points. As the pitch angle resolution is limited to  $2^{\circ}$  and the logarithmic scales will expand the small pitch angle region strongly, the average flux in the intervals  $0^{\circ}$ - $2^{\circ}$  and  $2^{\circ}$ - $4^{\circ}$  pitch angle has been used. Insignificant ripple of the contours at small pitch angles can thus be avoided.

The dashed curve at 1 keV shows the shape of an isotropic distribution. The value of the distribution function is lower by a factor of  $\sim 3$  at small pitch angles than at  $\alpha = 90$ , but the positive slope in the distribution is apparently very weak.

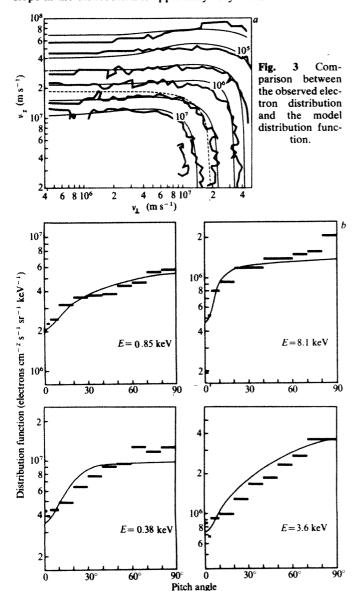

Table 1 Parameters of the complete model distribution

Component no.	Density (electron m <sup>-3</sup> )	Temperature (eV)	Δ	β
1 2	$5.5 \times 10^6$ $3.0 \times 10^6$	1 5	1	
3	$6.6 \times 10^4$	200	$\hat{0}.35$	0.15
4	$6.4 \times 10^4$	1,000	0.35	0.99
5	$5.1 \times 10^4$	8,000	0.40	0.02

A computer code can be used to estimate the growth rates of possible instabilities, if the measured distribution is modelled by a sum of components of the form<sup>12</sup>

$$f_{i} = \frac{\exp\left(-\frac{v_{z}^{2}}{V_{i}^{2}}\right)}{(\pi V_{i}^{2})^{3/2}} \left\{ \Delta_{i} \exp\left(-\frac{v_{\perp}^{2}}{V_{i}^{2}}\right) + \frac{1 - \Delta_{i}}{1 - \beta_{i}} \right.$$
$$\left. \times \left[ \exp\left(-\frac{v_{\perp}^{2}}{V_{i}^{2}}\right) - \exp\left(-\frac{v_{\perp}^{2}}{\beta_{i} V_{i}^{2}}\right) \right] \right\}$$

Here, the parameters  $\Delta_i$  and  $\beta_i$  measure the depth and width of the loss-cone, and  $V_i = (2T/m)^{1/2}$  is the thermal velocity. A model of this kind fitted to the observations is shown in Fig. 3. Figure 3a shows the contours of the model superimposed on the measured distribution. The differential fluxes as a function of  $\alpha$  are compared in Fig. 3b. It is not easy to assess the degree of agreement between model and measurement quantitatively, as the fit is done by trial and error. The model shown in Fig. 3 is close to the best obtainable using three components of the form above.

In addition to the three hot components, two maxwellian components are used to model the low-energy electrons. The parameters of the complete model distribution are given in Table 1.

The wave spectra have been calculated numerically by means of a computer code which solves the dispersion relation of waves in a magnetized plasma consisting of maxwellian components. The dielectric tensor of a maxwellian plasma can be expressed in terms of modified Bessel functions  $I_n$  and the plasma dispersion function Z (ref. 23). In the program, the dielectric tensor and its first derivatives with respect to  $\omega$ ,  $k_z$  and  $k_\perp$  are written as combinations of  $I_n$  and  $Z(\omega - n\Omega_e)/k_z$ . The full electromagnetic dispersion relation is then solved by iteration, using Newton-Raphson's method. Any two of the three variables  $\omega$ , k, and kcan be specified and solved for the third, but because k is taken to be real while  $\omega$  is complex, convergence can be ensured only when solving for  $\omega$ , and only this case will be considered here. The iteration stops when the relative error in the last estimate is  $<10^{-6}$ . We have then obtained a real frequency  $\omega_k$  and a temporal growth rate  $\gamma_k$ . However, to estimate the wave spectrum we need also the group velocity  $\mathbf{v}_{e}$ . The components of the group velocity are easily calculated from the derivatives of the dispersion relation, and the intensity amplification of the wave can be estimated as  $\gamma_k/v_g$  times the propagated distance.

When the wave propagates a distance I, the gyrofrequency will change by  $\Delta\Omega_{\rm e} \approx I \cdot \nabla \Omega_{\rm e}$ . As the unstable bandwidth is  $\sim 0.2~\Omega_{\rm e}$  (in all harmonic bands), the amplification will stop when

$$\left| \frac{\omega}{\Omega_{\rm e}} - \frac{\omega}{\Omega_{\rm e} + \Delta \Omega_{\rm e}} \right| \approx 0.2$$

In a dipole field we have  $\Delta\Omega_{\rm e}/\Omega_{\rm e} \approx 3l_{\rm r}/r_0$ , where  $l_{\rm r}$  is the distance propagated in the radial direction, and  $r_0$  is the distance from the Earth. This leads to

$$L_{\rm r} \approx \frac{0.2\Omega_{\rm e}}{3\omega} r_0$$

as the maximum radial distance over which the wave can be amplified. At  $r_0 \approx 6$   $R_{\rm E}$  and  $\omega \approx 3/2$   $\Omega_{\rm e}$ , this corresponds to  $\sim R_{\rm E}/4$ . However, the radial amplification length may not be very interesting, as the scale lengths parallel to the magnetic field and in azimuth are larger.

Experimental studies of the occurrence of these types of emission indicate that they are confined to within a few degrees of the geomagnetic equator<sup>7,10</sup>. Although the reasons for this close confinement to the equatorial plane are poorly understood, a maximum amplification length  $L_x = 2 L_t$  has been used in the calculations. This corresponds to a confinement within ~±2.5° of the geomagnetic equator. There is no way of determining the maximum amplification length  $L_{\perp}$  in azimuth from observations. As a reasonable estimate we chose  $L_{\perp} = 4 L_{r}$ . These estimates are very rough, but an accurate determination of the amplification lengths would require ray tracing in a magnetosphere where the variation of the plasma parameters in a large volume of space were known. As there is no experimental technique which measures the relevant parameters throughout a large volume, we must rely on such estimates, but note that the value of  $L_{\perp}$  chosen is compatible with the result of a simplified ray tracing in an idealized magnetospheric model<sup>12</sup>

Assuming that the wave growth is limited by propagation effects rather than some nonlinear saturation mechanism, we can calculate the shape of the frequency spectrum. At each frequency, we choose the k value which gives the strongest amplification within a region of space with dimensions  $L_{\perp}$  and  $L_{\rm r}$ . The amplification (in dB) is calculated as 8.7  $\gamma_{\rm k}$ ·min( $L_{\perp}/v_{\rm g}$ )  $L_z/v_{zz}$ ) and this amplification rate as function of  $\omega_k$  will give the approximate shape of the frequency spectrum. Absolute values of the spectral density cannot be calculated without specifying the initial level of fluctuations, but the relative strength of emissions at different frequencies can be compared with observed spectra.

The amplification predicted by the theory is compared in Fig. 4 with a measured frequency spectrum. The spectral density

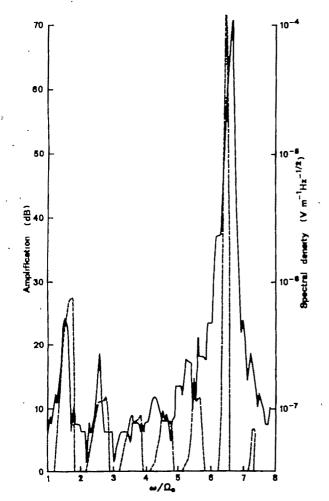

Fig. 4' Comparison between the spectral density observed by S-300 at 09 48 UT and the calculated amplification (dashed).

(solid line) was measured by the S300 experiment at around 09.48 UT on 25 August 1977. The density amplification (a dashed line) has been calculated using the model distribution function defined in Table 1. Although the exact positions of the peaks within the harmonic bands coincide poorly, the general shape of the measured spectrum is very well described by the calculated amplification. The theory correctly predicts that the strongest emission is near the upper hybrid frequency, with fairly high amplitudes around  $3/2 \Omega_{\bullet}$  and weaker signals in the intermediate harmonic bands. The upper hybrid amplitude of the very quietest emissions observed by GEOS 1 (ref. 9) is  $\sim 5 \times 10^{-6} \text{ V m}^{-1} \text{ Hz}^{-1/2}$ . Taking this value as a reasonable estimate of the background fluctuation level, we find that it is consistent with the 0 dB level chosen for the comparison in Fig. 4.

Two main types of error will affect the reliability of this comparison of theory and experiment, the most important source probably being the limited time resolution of the experiments. A measurement of the complete hot particle distribution cannot be made in <3 min, in which time all relevant parameters may vary significantly. As the low energy (0.3-1.5 keV) particles mainly involved in the instability were measured at the end of the period 09.45-09.48 UT, the spectrum chosen for the comparison has been taken near 09.48 UT to minimize the effect of time variations. However, a full frequency sweep is obtained in 22 s, and significant changes in the spectrum are often seen from one sweep to the next. This indicates that rapid variations are common, and the accuracy of the prediction is probably limited by these time variations. The second source of error is the rough estimate of the size of the amplification region. If the magnitudes of  $L_{\perp}$  and  $L_{\tau}$  are varied with the ratio  $L_{\perp}/L_{z}$  fixed, the maximum amplification at all frequencies will vary at the same rate. The amplification curve will be compressed or expanded but retain its general shape. Reasonably small changes in the ratio  $L_{\perp}/L_{\pi}$  should mainly influence the frequency of maximum amplification within each harmonic band, but small changes in the magnitude of the peaks might also occur. Compared with these two main difficulties, the errors introduced when modelling the distribution function and solving the dispersion relation are probably small.

The values of most parameters needed for this study have been determined directly from measurements, and the remaining values are at least consistent with observations. Given a set of input parameter values, it seems unlikely that the calculations would reproduce the observed wave spectrum so well if the essential physics were not included in the mathematical model. In particular, it seems possible to estimate the shape of the wave spectrum using linear theory if the particle distribution function is known. Quasilinear or nonlinear effects are apparently not required to limit the wave growth in this case, although the weakness of the gradients in the hot electron distribution may well be the result of quasilinear diffusion.

Considering the present results and those of Horne et al.20, our understanding of the linear theory of electrostatic electron cyclotron harmonic waves is probably approaching a point where quantitative predictions about wave spectra may be based solely on particle measurements. The experience of applying this methodology to a well chosen set of wave events should also enhance the possibilities of using wave measurements for magnetospheric plasma diagnostics.

This study has been performed within a large GEOS 1 collaboration and our colleagues have contributed to it in many ways. In particular we thank H. Borg, P. Gough and R. Horne for assistance in the data handling and valuable comments. This research was supported by the Swedish Board for Space Activities, the SRC and the ESA.

### Amplitude variations of electron cyclotron harmonic waves

R. B. Horne\*, P. J. Christiansen\*, M. P. Gough\*, K. G. Rönnmark†, J. F. E. Johnson‡, J. Sojka‡ & G. L. Wrenn‡

‡ Mullard Space Science Laboratory, University College London, Gower Street, London WC1E 6BT, UK

Electron cyclotron harmonic (ECH) instabilities just outside the plasmapause and at frequencies near the cold upper hybrid frequency are a common feature of the Earth's magnetosphere. These waves which have virtually no magnetic component, are believed to have an important role in the generation of weak diffuse aurora<sup>1,2</sup>. They are able to interact strongly with electrons in the hundred eV to several keV energy range which can result in pitch angle scattering and precipitation on magnetic field lines which map down into the auroral zone. On the dayside magnetosphere these waves can exhibit large amplitude variations of 30-40 dB and can also exist at steady amplitudes on time scales of the order of tens of seconds. Here we seek an explanation for the sporadic nature of such instabilities by performing linear stability calculations and extending the technique used in the accompanying paper3.

An example of the emissions recorded by GEOS 1 on 25 August 1977 is shown in the frequency time spectrogram of ref. 3. Figure 1 of ref. 3 shows that after 09.45 UT in that event, the signal in the band near the upper hybrid frequency  $f_{\rm uh}$  is accompanied by lower-frequency emissions at  $\sim 3/2$  and  $\sim 5/2$  times the electron gyrofrequency  $f_{ce}$  typical of spectra of class 3 in the scheme of Gough et al.4.

In the periods 09.48-09.50, 09.51-09.52 and 09.53-09.54 UT the second harmonic of the strongest emission appears together with signals in the extra low frequency (ELF) range. The second harmonic signal is an instrumental saturation effect indicative of large wave amplitudes >3 mV m<sup>-1</sup>. The ELF signal measured in the frequency range 15-450 Hz and detected by the same preamplifier also saturates and thus preamplifier saturation effects cannot be ruled out. However, studies of similar events on GEOS 15, have shown that ELF signals detected in unsaturated conditions are electrostatic with a spectral peak close to the lower hybrid frequency. Nonlinear wavewave couplings due to the strong  $f_{\rm uh}$  pump wave are thus implied.

Time variation of  $f_{uh}$  and ELF amplitudes are shown in Fig. 1, with changes in the energy density of electrons below 500 eV.

Electrons in the energy range 0.5-500 eV are measured by the S302 particle experiment<sup>6</sup> using two detectors, one looking along the satellite spin axis and the other at 80° to it. As the angle between the spin axis and the magnetic field was 18° during this event, pitch angles between 62° and 98° were covered by the second detector.

Analysis of the data from this instrument shows, after subtraction of photoelectron contamination, that the low energy electrons can be represented by four maxwellian components at temperatures of 1, 5, 60 and 200 eV. Only the 5-eV component shows sporadic variations which are seen preferentially in the nearly field-aligned detector. Summarizing the observations in terms of an energy density, this quantity is strongly anticorrelated with the strength of waves near  $f_{\rm uh}$  and ELF emissions as shown in Fig. 1. This suggests that the wave amplitude variations might be connected with changes in the distribution of lowenergy electrons.

Higher-energy electron fluxes between 350 and 22 keV, recorded by the S310 experiment, show remarkably little variation by comparison. Data taken at intervals of 6 min, and covering times of highly variable wave activity, reveal no significant changes in the hot electron distribution. The distribution shown in Fig. 2 of ref. 3 can thus be regarded as typical for the time period of interest here.

Using the techniques described in ref. 3, two electron distributions have been constructed, one (model A) appropriate to the period of strong wave activity 09.48-09.50 UT and the other

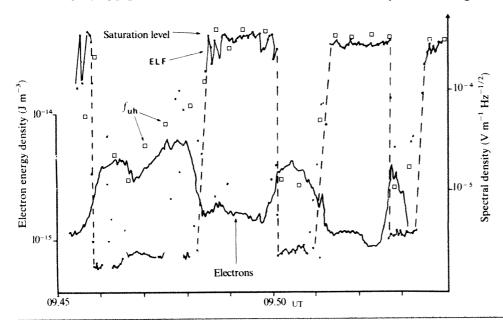

Fig. 1 Anticorrelation between the energy density of electrons below 500 eV and the amplitude of waves both in the ELF region and near the upper hybrid frequency fuh. A full pitch angle energy distribution is measured by the \$310 experiment between 09.45 and 09.48 UT. At 09.50 UT the satellite coordinates are LT = 11.20, L = 6.6, magnetic latitude = 10° and  $k_{\rm p} = 5$ .

<sup>†</sup> Kiruna Geophysical Institute, University of Umeå, S-901 87 Umeå, Sweden

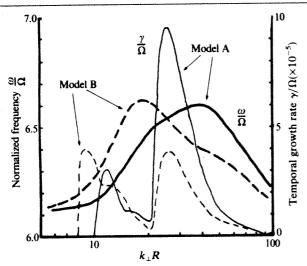

Fig. 2 Solution of the dispersion relation between the electron gyroharmonics  $6\Omega$  and  $7\Omega$ . The electron gyrofrequency is  $f_{\rm ce}=4.4$  kHz and the cold upper hybrid frequency is  $f_{\rm uh}=6.05f_{\rm ce}$ . The thick solid and dashed curves are the wave frequency for each model while the thin sharply peaked curves are the temporal growth rates. Calculated parameters include  $\alpha=52$ ,  $\Delta\omega=0.1$  for model A and  $\alpha=-22$ ,  $\Delta\omega=0.2$  for model B.

(model B) corresponding to weaker wave activity 09.45–09.48 UT. Both models use the same parameters derived in ref. 3 for the three highest energy components, while the low energy components have been remodelled from a more refined analysis of the low-energy particle data: model A consists of two isotropic maxwellians with temperatures and densities,  $T_1 = 1 \text{ eV}$ ,  $n_1 = 7.5 \times 10^6 \text{ m}^{-3}$ ,  $T_2 = 5 \text{ eV}$ ,  $n_2 = 1 \times 10^6 \text{ m}^{-3}$ . For the three components of model B the following values are used:  $T_1 = 1 \text{ eV}$ ,  $n_1 = 4.5 \times 10^6 \text{ m}^{-3}$ ;  $T_2 = 5 \text{ eV}$ ,  $n_2 = 3.5 \times 10^6 \text{ m}^{-3}$ ;  $T_3 = 10 \text{ eV}$ ,  $T_{3\perp} = 5 \text{ eV}$ ,  $n_3 = 5 \times 10^5 \text{ m}^{-3}$ . This last anisotropic component, plus the increased density of  $n_2$ , reflect reasonably well the increased fluxes at small pitch angles of suprathermal electrons which are presumably of ionospheric origin. The cold upper hybrid frequency is set at 26.6 kHz, a little lower than in previous preliminary reports.

The linear electrostatic dispersion relation for ECH wave propagation in a multi-component plasma has been solved numerically for complex frequency as a function of real wave vector components,  $k_{\perp}$ ,  $k_z$  are respectively perpendicular and parallel to the ambient magnetic field  $\mathbf{B}_o$ . The dependence of the normalized real frequency  $\omega/\Omega$  (where  $\Omega=2\pi f_{ce}$ ) is shown in Fig. 2 as a function of  $k_{\perp}R$  (R being the 200-eV electron Larmor radius of  $\sim 300\,\mathrm{m}$ ). Also plotted are the largest normalized temporal growth rates  $\gamma/\Omega$  taken for the unstable  $k_z$  R range.

A comparison of the two models shows that the enhanced 5-eV component in model B has moved the frequency maximum to smaller perpendicular wavenumbers and increased the perpendicular group velocity near  $k_{\perp}R \sim 30$ , where  $\gamma$  is large. Furthermore, increased cyclotron damping, caused by the additional 5-eV electrons, has reduced the temporal growth rate by a factor of 2 with respect to that of model A. However, the unstable waves predicted here have non-zero group velocities. They are convectively unstable and therefore the spatial growth rates must be considered to determine the final wave amplification levels<sup>10</sup>.

Spatial growth rates  $k_i$  can be calculated from the temporal growth rate and the group velocity  $(k_i = -\gamma/V_g, k_i \ll k_\perp)$ . The final amplification levels are estimated when the distance over which the amplifying waves propagate is known.

It is assumed that the plasma density variation is small over the relevant time scales and distances for convective growth.

Furthermore, changes in the dimensionless frequency  $\bar{\omega} = \frac{\omega}{\Omega}$  are assumed only to occur as the waves propagate through regions of

varying magnetic field (assumed to be dipolar). When the change in dimensionless frequency,  $\Delta \bar{\omega}$ , is such that the waves are effectively detuned from resonance, convective growth ceases and amplification is thus limited to a magnetospheric volume characterized by the three scale lengths  $L_{\rm r}$  in radius,  $L_{\perp}$  in azimuth (both in the plane perpendicular to  ${\bf B}_{\rm o}$ ) and  $L_{\rm z}$  parallel to the magnetic field. These parameters are now estimated for a dipole magnetic field.

The radial dimension  $L_r$  derived in ref. 3 is given below with the scale length  $L_{rp}$  due to plasma frequency variations assumed inversely proportional to  $R^2$  (ref. 11)

$$L_{\rm r} \simeq \frac{R_{\rm o}}{3} \frac{\Delta \bar{\omega}}{\bar{\omega}}$$
  $L_{\rm rp} \simeq \frac{R_{\rm o}}{2} \frac{\Delta \omega'}{\omega'}$ 

where  $\omega' = \omega/\omega_{\rm p}$ . In the model  $\Delta\bar{\omega}/\bar{\omega} = \Delta\omega'/\omega'$  and thus for the same percentage variation in  $\bar{\omega}$  and  $\omega'$  magnetic field variations yield the smallest scale length. Moreover calculations for different plasma densities show that the dispersion curves in the region corresponding to large temporal growth rates,  $k_{\perp}R = 30$ , are less sensitive to plasma density variations than the upper hybrid frequency is. Therefore magnetic field variations make  $L_{\rm r}$  the dominant quantity. The azimuthal dimension  $L_{\perp}$  is obtained by adopting the ray tracing method of Barbosa and Kurth<sup>12</sup> where the spatial variation of wave refractive index  $n(\bar{\omega})$  due to magnetic field changes is expressed as a power law in  $\bar{\omega}$ .

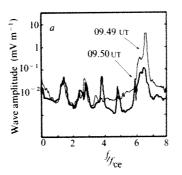

$$n(\tilde{\omega}) = \tilde{\omega}^{\alpha}$$

Here  $\alpha$  is the power index evaluated over the perpendicular wavenumber range corresponding to instability. The result is

$$L_{\perp} \approx R_{o} \left( \frac{8\Delta \tilde{\omega}}{3\tilde{\omega} (3.|\alpha| \pm 1)} \right)^{\frac{1}{2}}$$

where  $R_o=6.6$  Earth radii and the negative sign should be taken for  $\alpha>0$ . In the calculations  $\Delta\bar{\omega}$  is identified with the frequency bandwidth over which significant spatial amplification exists, with the results  $L_{\perp} \approx 600$  km for model A and  $L_{\perp} \approx 1,500$  km for model B. The parallel dimension,  $L_z$ , for this particular class of wave activity is taken from observations. Strongest signals have been reported to be confined to  $\pm 2.5^{\circ}$  about the geomagnetic equator<sup>4</sup>. More recent observations<sup>13</sup> show the confinement to be as small as  $\pm 1^{\circ}$  from which the value  $L_z=1,500$  km is used in these calculations. Note that equatorial confinement of the upper hybrid emission is probably due to a combination of refraction effects and loss of resonance in weak field gradients<sup>12</sup>.

Computations of the group velocities show that the waves traverse the amplifying region in a few tens of seconds at all frequencies except  $\sim 6.6~f_{\rm ce}$ . At this frequency, which corresponds to the maximum in the dispersion curves, the perpendicular group velocity changes sign while the parallel group velocity remains small. Predictions for model B then indicate that such a wave, which is essentially absolutely unstable, would remain in the amplifying region for some tens of minutes. That

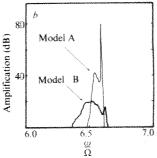

Fig. 3 Comparison between the observed wave spectra at 09.49 and 09.50 UT (a) and the calculated wave amplification between  $6\Omega$  and  $7\Omega$  (b). Strong electrostatic waves are not observed between  $7f_{ce}$  and  $8f_{ce}$  and the cold upper hybrid frequency is estimated at  $6.05 f_{ce}$  (see text).

this cannot happen can be seen from the observation that the duration of both strong and weak emissions is  $\sim 90$  s. After this period changes in the particle distribution remove the near absolute instability and increase both parallel and perpendicular group velocities.

Furthermore, detuning effects arising from wave propagation is the z direction, which are not considered in the ray tracing model above, will also occur.

The final amplification levels predicted for both models are shown in Fig. 3. Convective amplification levels have been calculated in the same way as in ref. 3 using the scale lengths deduced above. For frequencies corresponding to near absolute instability the temporal amplification is assumed to be limited to ~90 s, irrespective of whether the waves have traversed the amplifying region or not. Figure 3 also shows wave spectra representative of the two emission levels.

The prediction for model B is a spectrum peaking at the 20-dB amplification level, while that of model A exceeds it by at least 20 dB and rises to a maximum of 80 dB amplification. A significant difference is also seen in the natural wave spectrum where the maximum amplitude levels in the  $6-7f_{ce}$  band for the strong emissions (corresponding to model A) exceed that of the model B related intermediate level emissions by at least

We conclude that the model used in this study includes the main features necessary to explain the sporadic transitions between the intermediate  $(E > 100 \,\mu\text{Vm}^{-1})$  and large amplitudes  $(E > 3 \text{ mV m}^{-1})$  typical of dayside ECH emissions. These transitions are due to subtle changes in the thermal and suprathermal electron populations, and this emphasizes that detailed understanding of such emissions requires accurate information about the distribution of the suprathermal population as well as that of the 'free-energy' source. Furthermore, even if there are small changes in the free energy source, the prediction of such a large difference between the maximum model amplification levels suggests that this conclusion remains unchanged. Further calculations designed to test the sensitivity of the models to small variations in the value of the cold plasma density support these conclusions. Predictions for  $\omega_{uh}$  as low as 5.8 $\Omega$  show that the difference between the maximum amplification levels in the 6-7 $\Omega$  band is maintained, whereas for  $\omega_{uh} > 6.6\Omega$  there is virtually no difference between the levels in the  $6-7\Omega$  band but large amplitudes are also predicted above  $7\Omega$ . As strong emissions above  $7\Omega$  are not observed experimentally, we conclude that  $\omega_{uh}$  lies close to  $6\Omega$  and that the value used here of  $\omega_{\rm uh} = 6.05\Omega$  is realistic.

Finally, we point out that many observations of strong sporadic emissions have been made using the GEOS 2 satellite, and the appearance of suprathermal, approximately fieldaligned electron components, presumably of ionospheric origin, often show strong anticorrelation with the upper hybrid band emission amplitudes.

We thank Mrs E. J. Gershuny for help in data handling and Dr G. Martelli for his interest. This research is supported by SRC, the Swedish Board for Space Activities and the ESA.

The crystal structure of a high silica zeolite ZSM-39, unit cell composition excluding residual water and occluded materialstetramethylammonium ion, tetraethylammonium ion)<sub>0.4</sub>(AlO<sub>2</sub>)<sub>0.4</sub>(SiO<sub>2</sub>)<sub>135.6</sub>, was determined by X-ray powder diffraction. The framework is pseudoface-centred, pseudocubic with  $a = 19.36 \pm 0.02 \text{ Å}$  and ideal symmetry Fd3m. The framework consists of a space-filling arrangement of pentagonal dodecahedra and hexakaidecahedra and is isostructural with the 17 Å cubic gas hydrate. The ZSM-39 framework is composed entirely of five- and six-rings which limits its sorptive and exchange properties. However, the large fraction of five-rings and the high Si/Al ratio (>40) impart a high thermal stability. ZSM-39 containing no aluminium constitutes the end member composition. Although ZSM-39 is the only synthetic zeolite analogue of a gas hydrate, we propose here two related hypothetical frameworks containing pentagonal dodecahedral cages.

The analogy between hydrogen bonds linking oxygens in clathrates and oxygens linking T-atoms in aluminosilicate framework structures is well known. Hexagonal ice I and ice Ic are isostructural with  $\beta$ -tridymite and  $\beta$ -cristobalite respectively<sup>1</sup>, HPF<sub>6</sub>·6H<sub>2</sub>O and (CH<sub>3</sub>)<sub>4</sub>N(OH)·5H<sub>2</sub>O are isostructural with sodalite<sup>2,3</sup> and the rare mineral, melanophlogite<sup>4-6</sup> is isostructural with the 12 Å cubic gas hydrate<sup>7,8</sup>. ZSM-39 is the first zeolite which is isostructural with the 17 Å cubic gas hydrate<sup>9,10</sup>.

ZSM-39 was synthesized hydrothermally in a system containing tetramethylammonium and tetraethylammonium hydroxide, silica, and sodium aluminate. Crystallization was at ~155 °C and was complete after 330 h (ref. 11). Analysis of a ZSM-39 sample gave (wt% composition): SiO<sub>2</sub>, 89.0%; Al<sub>2</sub>O<sub>3</sub>, 00.2%; Na<sub>2</sub>O, 00.3%; N, 00.8%; C, 03.76%. The remaining 5% could not be accounted for with complete confidence. The analytical data refer to the as-synthesized material before calcination. In this state the unspecified difference can be attributed primarily to water and hydroxyl groups.

Crystals of ZSM-39 tend to have octahedral habit as shown in Fig. 1. Single crystals > 10 μm could not be grown. ZSM-39 has

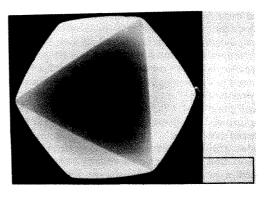

Fig. 1 Scanning electron micrograph of ZSM-39 single crystal. The habit suggests cubic symmetry. ×4,500.

little zeolitic sorptive capacity even after calcination at high temperatures. The material becomes black on calcination indicating that carbonaceous material is being retained in the pore structure. The same effect is observed with melanophlogite<sup>1</sup>. The thermal stability is very high and crystallinity is retained even after calcination at temperatures above 800 °C.

X-ray diffraction patterns of ZSM-39 were obtained using a Norelco powder diffractometer and  $CuK\alpha$  radiation. Powder diffraction data are given in Table 1.

Morphology, X-ray powder, and sorption data were used to determine the structure. Morphological evidence indicative of cubic symmetry was confirmed by analysis of the powder pattern and a cell parameter of  $19.36\pm0.02$  Å (D. H. Olson, personal communication) was obtained by least-squares refinement using 39 indexed reflections. Except for a few very weak lines, all reflections attributable to ZSM-39 are consistent with Fd3m symmetry. The high symmetry and lack of sorptive capacity suggested a clathrate-like structure. Examination of these structures revealed that the 17 Å cubic gas hydrate had ideal symmetry Fd3m. This structure has an average lattice constant of 17.2 Å and a hydrogen bond distance of 2.73 Å. Assuming an

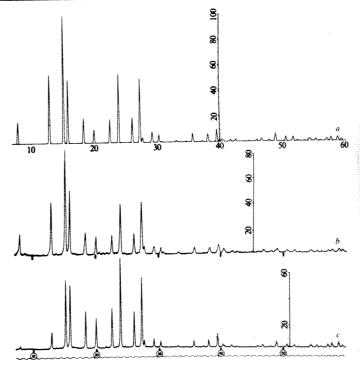

Fig. 2 a, Simulated powder pattern of the ZSM-39 framework. b, Powder pattern of ZSM-39 (sample after calcination for 0.5 h at 800 °C). c, Powder pattern of ZSM-39 (sample as synthesized).

Si—O—Si bond distance of 3.07 Å, the postulated adjusted cell parameter of the silica analogue would be 19.34 Å which compares well with the observed value of 19.36 Å for ZSM-39.

Least-squares atomic positions for the T and oxygen atoms, obtained using the DLS method<sup>12</sup> are given in Table 2. A Smith plot<sup>13</sup> obtained using these coordinates is compared with an X-ray powder pattern of ZSM-39 in Fig. 2. The agreement indicates that the ZSM-39 framework is topologically equivalent to that of the 17 Å cubic gas hydrate.

A number of very weak reflections inconsistent with a facecentred lattice indicated that the symmetry of ZSM-39 is lower than Fd3m. This is similar to the situation with melanophlogite<sup>14</sup>.

The framework of ZSM-39 consists of 12-hedra (pentagonal dodecahedra) and 16-hedra (hexakaidecahedra) as shown in Fig. 3. The structure is composed of layers of face-sharing 12-hedra arranged as in Fig. 4a. In ZSM-39 these layers are stacked in an ABC sequence. The framework may be alternately viewed as 16-hedra linked tetrahedrally through common sixrings. The arrangement of 16-hedra is the same as that of the carbon atoms in diamond.

The layers of ZSM-39 (Fig. 4a), may also be stacked in an AB sequence, giving rise to a hypothetical framework with ideal

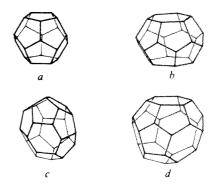

Fig. 3 Polyhedral building units of the ZSM-39 and melanophlogite structures. a, 12-hedron (dodecahedron); b, 14-hedron (tetrakaidecahedron); c, 15-hedron (pentakaidecahedron); d, 16-hedron (hexakaidecahedron).

symmetry, P6m2, and cell parameters of a = 12.2 and c =24.2 Å. This structure contains the same polyhedra as ZSM-39. These two frameworks are the simplest members of a polytypic

Melanophlogite, the first reported silica analogue of a gas hydrate, has a framework consisting of interwoven layers of 12and 14-hedra (Fig. 3). In contrast to ZSM-39, this framework contains isolated 12-hedra (Fig. 4b). Sliding alternate layers a distance of a/2 results in a hexagonal framework with ideal symmetry P6/mmm and a = 13.6 and c = 14.0 Å. This hypothetical framework consists of a space-filling arrangement of 12-, 14-, and 15-hedra (Fig. 3). Although there is no known zeolite of this type, (i-C<sub>5</sub>H<sub>11</sub>)<sub>4</sub>NF · 38H<sub>2</sub>O does adopt this structure<sup>3</sup>

Porotectosilicate analogues of water-clathrate structures which typically consist of cages comprising pentagonal rings constitute a new family of high-silica materials, most of which are still hypothetical. ZSM-39, the first synthetic member, should encourage further attempts to synthesize other members of the family including melanophlogite, a small molecule trap that has long intrigued mineralogists.

We thank D. H. Olson, S. L. Lawton, and P. Chu for assistance, J. B. Milliken and A. C. Rohrman Jr for density data and SEM micrographs, also G. A. Jeffrey and D. E. Appleman for their valuable discussions regarding clathrates and melanophlogite, respectively. W.M.M. acknowledges the support of the Swiss NSF.

### Hydrothermal leaching of rhyolite glass in the environment has implications for nuclear waste disposal

A. P. Dickin\*

Department of Geology and Mineralogy, University of Oxford, Oxford OX1 3PR, UK

Glass has been widely advocated as a suitable medium for the immobilization of high-level nuclear waste1-6. Methods of vitrification to borosilicate glass are advanced, with processes set up on a semi-industrial scale<sup>7-9</sup>, but an alternative strategy would be to incorporate waste into a high-silica glass<sup>10</sup>. It is generally proposed5.6 that vitrified radioactive waste be enclosed in metal canisters and stored underground. However, the presence of heated groundwater in rocks means that the canisters may corrode, allowing hot aqueous fluids to come into contact with the radioactive waste glass and leach out radioactive elements. Numerous laboratory tests have been performed for short periods and at relatively low temperatures to assess the leaching performances of different types of glass 11-15, however, extrapolation to predict the long-term behaviour of glasses after burial is very uncertain. I report here a microprobe analysis technique which investigated hydrothermal leaching of rhyolite glass adjacent to a fluid conduit in the Tertiary hydrothermal system of the Isle of Skye, north-west Scotland. As the composition of rhyolite and proposed high-silica radioactive waste glasses are similar, this study may help to predict the long-term leaching behaviour of such glasses after underground burial.

Fractures which formed fluid conduits for the Skye hydrothermal system have been plugged by secondary mineral growth, and now form veins which cut through the rocks. The analysed sample is cut by such a hydrothermal vein, and comes from near the centre of an acid/basic composite sill. This was exposed in 1979 in a roadstone quarry at Sconser (NG 544 318) on the Isle of Skye (Fig. 1b). The sill is intruded into the late Precambrian 'Torridonian' arkosic sandstones only 300 m from the northern margin of the Western Redhills centre of granitic

<sup>\*</sup> Present address: Scottish Universities Research and Reactor Centre, East Kilbride, Glasgow G75 0QU, UK.

intrusion<sup>16</sup>. A gravity survey<sup>17</sup> (Fig. 1c) suggests that the margin of the granite complex is almost vertical, and passes directly downwards into the margin of a massive basic pluton underlying Skye. The heat evolved from this body drove a huge meteoric-hydrothermal convection system, whose existence is demonstrated by very depleted <sup>18</sup>O compositions in the rocks in and around the central complex<sup>18</sup>. These  $\delta^{18}$ O compositions closely resemble those in the vicinity of the Skaergaard intrusion of Western Greenland<sup>19</sup>, suggesting that numerical modelling of the Skaergaard hydrothermal system<sup>20</sup> is applicable to Skye.

Epidote-calcite veins which cut Torridonian sandstone in Sconser quarry continue through the Tertiary sill without interruption, indicating that a single hydrothermal event affected both sill and country rocks. Therefore, the sill must have been subjected to the full duration of the hydrothermal convection system generated by the plutonic complex. Veins are predominantly aligned radially to the Redhills complex, and those which are similar in size to the studied example have a separation of ~10 cm (ref. 21). Assuming a separation of 10 cm between parallel planar fractures, comparison with Norton and Taylor's S2 numerical model of the Skaergaard suggests an integrated fluid flux of over 10,000 lper cm-fracture-length, almost all of which occurred in an initial 200,000 yr period at -400 °C. An integrated flux of this magnitude provides an effectively open system for alteration of the fracture wall rocks, ruling out the possibility that fluid composition could be buffered within the sill.

The presence of tridymite in the Coire Uaighneigh Granophyre of Skye led Brown<sup>22</sup> to deduce a value of 1.5 km for maximum post-Tertiary erosion of the Skye lava pile. As Scon-

Country rocks: light stipple, Lewisian (Archaean) gneiss; heavy stipple, Torridonian sandstone; black, Mesozoic sediments. Horizontal and vertical distances in km.

ser quarry lies near sea level, this suggests that the hydrothermal vein under investigation was at a depth > 1 km, corresponding to a lithostatic pressure of 0.3 kbar or a hydrostatic pressure of 0.1 kbar. The actual pressure in the vein was probably between these two limits.

A low-power photomicrograph of the vein (Fig. 2a) shows it to be a nearly planar, sharply bounded fracture, 0.9 mm wide, filled by large sparry calcite crystals and fringed by epidote. This vein must once have been an open fissure, as euhedral prismatic epidote crystals grow out from the walls into the free space of the fracture (Fig. 2b).

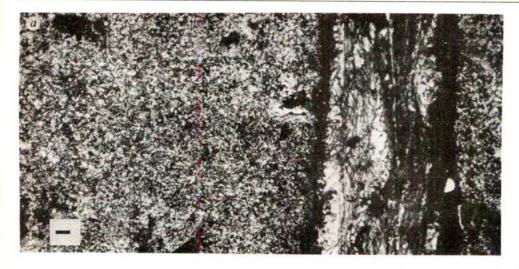

Figure 2c shows wall rock material a few mm from the vein under high power and crossed polars. Aggregates of small alkali feldspar and quartz crystals are interspersed by patches of a more isotropic matrix, showing that the microcrystalline felsitic texture of the rock was produced by devitrification of an original glass. The grainsize of the felsite falls slightly in a zone of bleached rock within 1.5 mm of the fracture. Devitrification of the original glass probably occurred during the period of hydrothermal metamorphism, rather than before or after. In this period, the presence of hot fluids would have speeded up kinetic processes of recrystallization. Figure 2d shows a map of K distribution in the felsite which picks out the distribution of alkali feldspar.

A polished section of typical wall-rock material, perpendicular to the plane of the fracture, was analysed using an electron microprobe (Cambridge Scientific Instruments Microscan 9). The probe beam of  $6\times10^{-8} A$  at  $20\,\mathrm{kV}$  was rastered over  $100\,\mu\mathrm{m}\times100\,\mu\mathrm{m}$  squares, which were analysed in 2.5 mm long strips, stretching from the vein wall into unbleached material. Twelve adjacent strips were analysed, and mean compositions were calculated for each increment of distance away from the vein. For each oxide, results outside two standard deviations from the mean were rejected, and if three or more oxides were thus excluded then the whole analysis was discounted. This procedure was adopted in an attempt to remove the effects of microphenocrysts from the felsite analyses. The area analysed was chosen for the absence of adjacent large phenocrysts.

Modal mineral analyses were determined by 'point counting' at  $40 \mu m$  intervals, using 2,500 partial microprobe analyses. The beam was focused to spot, resulting in an analysis area of a few square micrometres. The zone thus analysed was the same as for the whole-rocks.

Whole-rock microprobe analyses are plotted in Fig. 3 as profiles of oxide weight percentages against distance from the vein wall. As the vein is approached,  $SiO_2$  and MgO contents plunge, while  $Al_2O_3$ , CaO and  $Na_2O$  rise. These compositional variations extend up to a distance of  $\sim 1.5$  mm from the vein wall, beyond which major-element variations are not correlated with distance. Contents of  $K_2O$ , MnO,  $P_2O_5$ , SrO and BaO remain essentially constant from 0 to 2.5 mm from the vein, while total iron (expressed as FeO) and  $TiO_2$  vary rather erratically, due to the uneven distribution of titanomagnetite microphenocrysts (Fig. 2a).

To quantify the oxide variations as a function of distance from the vein, weight percentages have been regressed against distance, and correlation coefficients calculated. The results are shown in Table 1. Contents of SiO<sub>2</sub> and MgO display very strong positive correlations with distance from the vein, while Al<sub>2</sub>O<sub>3</sub>, CaO and Na<sub>2</sub>O display very strong negative correlations with distance. SiO2, Al2O3, CaO and Na2O form essentially linear trends between 0 and 1.5 mm from the vein, while MgO drops dramatically at 1.0 mm, before bottoming out within 0.5 mm of the vein. FeO and deficit-of-totals-below-100% (=H<sub>2</sub>O+CO<sub>2</sub>) correlate more weakly with distance from the vein, while the correlation of TiO2, K2O, SrO and BaO with distance is highly insignificant. The theoretical composition of the vein wall is calculated from the intercept of the regression lines at 0.0 mm from the vein, while the mean composition of felsite between 1.8 and 2.5 mm has also been calculated. The latter compares quite closely with the composition of 'world average rhyolite' (Table 1)<sup>23</sup>. The silica content at the vein wall (0.0 mm) is 9.34 wt% less

than in the unaltered material (1.8-2.5 mm), while the maximum enrichments of  $\text{Al}_2\text{O}_3$ , CaO and  $\text{Na}_2\text{O}$  at the vein wall sum to 9.14%. However, the build-up of these oxides cannot be a relative concentration effect caused simply by silica removal, because the enrichment factors (as a proportion of the fresh material) are different for each oxide (Table 1).

Whole-rock compositional variations in the vicinity of the vein are ascribed to exchange of species between the wall rocks and meteoric-hydrothermal fluids passing up the vein. Nevertheless, it is not immediately clear whether the changes are a product of fluid composition, or of mineralogical constraints. To assess the effects of mineralogy on whole-rock composition, modal mineral determinations were made by microprobe 'point counting'. The results are shown in Fig. 4. The abundances of calcite, epidote, quartz and alkali feldspar display correlations with distance in the region 0–1.5 mm from the vein, while beyond this distance the profiles are essentially flat. These

results are consistent with the whole-rock analyses and have similarly been regressed against distance from the vein (see Table 1).

Modal alkali feldspar content rises from an average value of 74.3% (1.8–2.5 mm from vein) to a value of 90.7% at the vein wall. Similarly, epidote increases from 0.8 to 7.5% and calcite rises from 0.5 to 1.1%. In contrast, the modal quartz content falls from 22.1% to a calculated value of -0.7% ( $\pm 1.8$ ) at the vein wall. All these elements correlate very strongly with distance from the vein (>99% confidence), but modal oxide contents do not correlate with distance at all ( $r^2 = 0.21$ ). Normative mineralogies calculated from the whole-rock compositions are consistent with modal mineral abundances. However, separation of alkali feldspar into its orthoclase and albite components shows orthoclase to be constant (31%) with distance, while albite rises sharply from 35 to 57% as the vein is approached.

ND, not determined.

Between 1.8 and 2.5 mm from the vein, devitrification of glass was isochemical, and formed a typical 'granitic' mineralogical assemblage of alkali feldspar and quartz with a subordinate hydrous ferromagnesian component. However, in the conditions of high water/rock ratio found at the vein wall, albite growth was particularly favoured. This developed by devitrification of glass, but also 'scavenged' additional Al2O3 and Na<sub>2</sub>O from hydrothermal fluids. In contrast, silica in the glass which was in excess of the requirements of alkali feldspar was removed by hydrothermal fluids as fast as devitrification occurred, and was not able to form quartz. The development of K feldspar seems to have been independent of water/rock ratio, as it is effectively the same at the vein wall as between 1.8 and 2.5 mm from the vein. This may also explain the flatness of the BaO profile, as the Ba<sup>2+</sup> ion is too big to fit into albite but is readily incorporated into orthoclase<sup>24</sup>. Epidote growth was strongly favoured at the vein wall, and incorporated iron, SiO<sub>2</sub>, Al<sub>2</sub>O<sub>3</sub> and CaO from the glass, but 'scavenged' additional CaO from hydrothermal fluids. The abundance of CaO in these fluids is indicated by the plugging of the vein with calcite, which does not form a major component in the altered wall rock.

McCarthy et al.25 noted that most leachability tests on borosilicate glass are conducted at 25 °C and 1 atm, whereas temperatures<sup>26</sup> in underground waste repositories could reach 400 °C. In view of these dangers, the proposed radioactive waste content of glasses has been reduced from its original 25% (ref. 11), but the cores of full size 'production' waste blocks will almost certainly exceed temperatures of 100 °C for long periods of time. In these conditions it cannot be assumed that the metal canister enclosing a waste block will not be breached by corrosion. Observed fracture development in such blocks yields glass lumps of average radius 5 cm (ref. 27), and ensures that if such a breach does occur then fluids can penetrate to the high-temperature core of the waste block.

A leaching experiment on 11-yr old 'Fingal' radioactive waste glass at 90 °C and 1 bar revealed 0.0023 g cm<sup>-2</sup> of leaching in 1 week, yielding an estimated linear leaching rate of 40 cm in 1,000 yr (ref. 11). This would be sufficient to disintegrate a waste block fractured into 5-cm radius pieces in <100 yr. Similarly, McCarthy et al. 25 found that 4-mm spheroids of simulated-waste borosilicate glass broke into fragments and 'seemed to be totally

altered' after only 2 weeks at  $\sim 300$  °C and 300 bar. In contrast, integration of the degree of oxide depletion in the rock analysed in this work, between the vein wall and a distance of 1.5 mm away, indicates that the total quantity of material leached by fluids per cm2 of vein wall was 0.019 g. This occurred in the presence of a high fluid flux at 400 °C and 300 bar, which lasted perhaps 200,000 yr. These comparisons show that high-silica glass has a much higher resistance to high temperature hydrothermal leaching than borosilicate glass.

Karkhanis et al.15 found that disks of rhyolite glass leached with heated distilled water produced large amounts of musco vite, whereas those reacted in the presence of granite shor only a small amount of crystalline product which appeare feldspar. This observation is consistent with the presof alteration processes; formation of the stable spar/epidote alteration assemblage being my 'scavenging' of Ca2+, Na+ and Al3+ from hyd Sconser, the hydrothermal fluids must species by interaction with the ark country rocks. These sediments he granite eutectic28, suggesting the favourable geochemical env radioactive waste glass. It is important to as

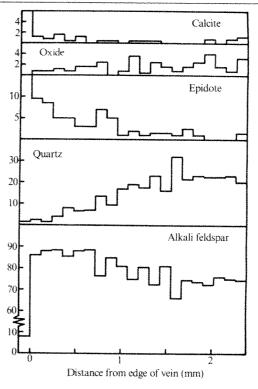

Fig. 4 Modal mineral percentages as a function of distance from vein.

slight enrichment of SrO as the vein is approached here (Table 1) shows that feldspar successfully incorporated Sr released by glass devitrification. Growth of potash feldspar enabled similar incorporation of the heavy fission product barium (Table 1). In the most severely altered material near the vein, epidote is a major hydrothermal mineral phase. Studies of hydrothermal borehole mineralogy<sup>30</sup> indicate that conditions for epidote growth have been achieved in the natural environment at depths of only 450 m. Analyses of the epidote group mineral allanite, which has grown in hydrothermal conditions in Skye31, reveal massive concentrations of actinides, rare-earth elements and strontium. The large A sites in this mineral can readily accommodate and trap LIL radioactive elements released during glass devitrification. Thus a new stable hydrothermal mineralogy can develop which will incorporate radioactive elements. However, glass must retain its structural integrity long enough for this hydrothermal mineralogy to develop.

This reveals the deficiency of borosilicate glass; the solubility of the borate fraction is such that it is readily removed from the system, causing the glass to disintegrate, and the radioactive elements to be released uncontrollably. Hence a lower borate fraction in radioactive waste glass will clearly result in greater resistance to leaching. Because borates form a flux for the melting process, their removal will necessitate higher furnace temperatures. However, if a colloidal solution of nitrates, with components present in similar porportions to the rhyolite eutectic, is evaporated, then dry melting should be possible at little over 1,000 °C (ref. 32).

That rhyolite glass retains its structural integrity and displays low solubility rates even when subject to devitrification and prolonged high temperature hydrothermal leaching indicates that high-silica glass is more suitable for long term disposal of radioactive wastes than borosilicate glass. Although high-silica glass requires a greater furnace temperature for melting, the extra cost involved may be outweighed by its stability advantages over borosilicate glass.

I thank R. A. Exley for advice in the field, S. Moorbath for helpful comments, the late R. Holland for preparation of the polished section, and P. Jackson and C. Fagg for advice on SEM and microprobe techniques. Microprobe research at Oxford is supported by the NERC and I thank University College Oxford for a Weir Junior Research Fellowship, and the Department of Geology and Mineralogy for financial support.

The fission track method has become acceptable in geochronology, not only in straightforward dating of igneous and metamorphic events but also in stratigraphic studies by the dating of ash layers1,2, the elucidation of crustal uplift history3and in archaeology8. Such studies have mostly used accessory minerals such as apatite, sphene and zircon, whose track-retentive properties are well documented. However, fission tracks can be developed and observed under the optical microscope in most minerals<sup>9-11</sup>. We report here on reconnaissance studies of fission track dating of zeolites, a complex group of tectosilicates, which is, for example, widely developed in basaltic rocks after their emplacement by later stage processes. We describe the etching conditions for some zeolites, in particular the minerals chabazite, stilbite and heulandite12 and detail the track recording and retention characteristics for chabazite, with particular reference to fossil hydrothermal systems in the Faeroe Islands.

Fleischer et al. 13 have previously reported the general etching conditions for zeolites. We have particularly investigated the effect of NaOH and KOH on chabazites. Homogeneous, inclusion-free chabazite crystals were annealed at 540 °C for 2 h

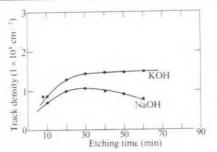

Fig. 1 Etching rates of chabazite for NaOH and KOH.

to erase all spontaneous tracks, mounted in epoxy resin and mechanically polished. The chabazite crystal structure only breaks down at 840 °C (ref. 14). Artificial tracks were then created using a  $^{252}$ Cf source in a  $2\pi$  geometry and the chemical etching was carried out in two groups for various times using boiling NaOH and KOH. The results (Fig. 1) indicate that with NaOH a maximum is reached, followed by a decrease in track density due to the progressive removal of surface layers of changed crystal. In the case of KOH (some typical etch pits are shown in Fig. 2) a plateau, reached after a relatively short time, remains constant. These relationships are due to differences in the velocity of etching along the tracks  $(V_t)$  relative to that for the bulk solid  $(V_g)$ . The ratio  $V_t/V_g$  is high for KOH but is much lower for NaOH. Note that uranium in chabazite is generally not considered to be an exchangeable ion.

Because thermal events may affect the final fission track 'age' of a sample we have carried out experiments both to evaluate this effect and to provide a calibration curve: chabazite is used as an example. If samples containing fission damage trails are subject to some thermal event and thereby lose a certain fraction of the tracks, they will appear to have decreased ages. Strozer and Wagner<sup>15</sup> proposed a method of correction for thermally lowered track densities, using calibration curves of residual track density as a function of average length of etch pit, both quantities being expressed as fractions of their unannealed values 16-18. After annealing a chabazite at 520 °C for 6 h induced tracks were created at a thermal neutron dose of 1015 (nvt). The fragment track density was then determined by etching aliquots which had undergone heat treatments varying from 100 to 500 °C (±5 °C) for 1 h. Etching through cleavage [1011] and [1101] planes was used to reveal the full track lengths. The length was evaluated by measuring both track dip and projected length, and phase contrast methods were used to enhance precision. An average of 'major' and 'minor' axes for each etch pit was recorded as the corresponding 'etch pit length'. For almost 11,000 etch pits scanned, between 800 and 900 track lengths were measured. Figure 3a shows the relationship between reduction in track density and length as a function of

 $\rho_s$  is the spontaneous track density;  $\rho_i$  the induced track density; n, the thermal neutron dose (nvt); N the number of grains counted; R the correlation coefficient.

temperature. This information gives an immediate estimate of the degree of fading of the spontaneous tracks and hence the age reduction provided that the track lengths are measured. Chabazite has a measured average track length of 11.8± 2.1 µm. At 100 °C, a slight decrease of ~2.8% in the track density and ~3.5% in the mean track length of etch pits was observed. At higher temperatures, the track length decreased more rapidly than the track density. After 1 h at 500 °C constant temperature the track density was reduced by 57.3% and the track length by 78.3% After 1 h at 600 °C all the tracks were annealed out. The reduction in track density was observed to lag behind that of track length (Fig. 3a). U<sup>235</sup>-induced fission tracks in both unannealed and annealed samples were measured. The shrinkage in track length, plotted as a function of track density reduction, yields the appropriate calibration relationship. The ratio of mean etch pit length of annealed and unannealed fission tracks is shown as a function of the percentage of fission track density reduction in Fig. 3b. The resulting calibration curve has been used to correct thermally-lowered fission track ages of chabazite (estimated correction is ~3%). Studies of various etchants for stilbite and heulandite resulted in the use of 2% HF at 23 °C for 20-30 s and 10 ml aqua regia: 1 ml 2% HF at 23 °C for 30-50 s respectively for these two minerals.

The zeolite specimens were dated by the (EDM) detector method<sup>19</sup>, samples of chabazite, stilbite and heulandite being sandwiched between muscovite mica detectors for measuring the induced tracks. The integrated thermal neutron dose to which the samples were exposed was itself determined by irradiating calibrated glass dosimeters with each consignment of

zeolites. Each glass dosimeter (supplied by R. Fleischer) was fractured and the fresh surfaces were etched with newly prepared 20% HF for ~30–35 s at 23 °C to obtain well defined, easily distinguished etch pits, ~800–1,000 pits being scanned for each consignment. The surface density of etch pits was measured and the integrated neutron flux calculated using the calibration relation<sup>20,21</sup>, and a factor of  $2.26 \times 10^{11}$  neutrons per track. Sample numbers 1, 3, 9 and 10 were again dated where muscovite detector was used for neutron dose measurement. Thermal neutron dose was determined by counting tracks in muscovite detector irradiated in contact with standard NBS glasses SRM-962 and SRM-963 (Cu values)<sup>22</sup>; the values obtained agreed with the independent measurements made on Au foil. The analytical results are in accord with the age results given in Table 1.

An investigation of the general relationship between track counting on internal mineral surfaces and that on external detectors was also made to determine the geometric factor  $^{23}$  for the use of external detectors with zeolites. For the zeolites studied the geometric factor varied between  $0.51\pm0.02$  and  $0.57\pm0.03$ , assuming the etching rate and the counting efficiency for external detectors to be the same for each zeolite, and the track shape to be virtually the same. However, etching of tracks lying in different orientations was highly anisotropic, giving rise to etch pits of varying topographic appearance. The constants used in the age calculations were  $\lambda_f = 6.8 \times 10^{-17} \text{ yr}^{-1}$ ,  $I = 7.223 \times 10^{-3}$ ,  $\sigma = 5.802 \times 10^{-22} \text{ cm}^2$  and  $\lambda_d = 1.551 \times 10^{-10} \text{ yr}^{-1}$ . Errors were calculated according to the method of McGee and Johnson<sup>24</sup> and Naeser *et al.*<sup>25</sup>, expressed in 1 s.d.

The exposed part of the Faeroe Islands consists of up to 3 km of largely basaltic lavas divided into a lower, middle and upper series by stratigraphic marker horizons. There are distinct mineralogical and geochemical differences throughout the pile (see refs 26-29). The lithologies show that significant time gaps separated the three series, but this has not shown up in radiometric dating, where variable ages between  $49.2 \pm 1.5$ - $60.4 \pm 1.4$  Myr were obtained<sup>30</sup>. Subsequent refinement of these data<sup>31</sup> suggests that the Faeroese lava pile from the bottom of the lower to the top of the middle series was erupted in the interval  $55.2 \pm 1.0 - 54.6 \pm 1.2$  Myr ago.

Fission track results for chabazite, stilbite and heulandite are shown in Table 1 for samples shown in Fig. 4 where a spread of ages from  $40.8\pm1.3$  to  $55.4\pm2.5$  Myr have been found. The oldest values occur in the lower series and the youngest in the upper series. However, we have no other evidence to contradict the K-Ar results which indicate a relatively short time span for the volcanic activity, consistent with results from the contemporaneous East Greenland and lavas<sup>32</sup>. The observed distribution is probably regional, with the youngest ages in the northeastern part of the islands, reflecting a more prolonged cooling in that region. Ages from the lower series on Suduroy and Mykines, which are close to the accepted age of volcanism, indicate that in the south and west of the islands the lavas underwent rapid cooling either as a result of lack of burial by significant amounts of overlying material, or as a result of a very rapid uplift. Such rapid uplift is probably due to the domeshaped structures believed to be present offshore to the northwest of Mykines and under Suduroy<sup>33</sup>. These domes, although occurring on a much smaller scale, invite comparison with East

Greenland, where a large domal uplift<sup>34</sup> was raised shortly after the basaltic volcanism and rapidly dissected by erosion4.

The annealing experiments reveal that the thermal stability of tracks in chabazite is lower than that in sphenes, garnet, epidote, allanite and hornblende<sup>35</sup>. Data from both annealing experiments and track shrinkage suggest that ages determined by applying the fission track method to zeolites will be slightly affected by thermal annealing. We assume in fact that the tracks became stable rather suddenly. Nevertheless, our study certainly indicates that the fission track method is suitable for zeolite dating. Work on the Faeroese zeolites will continue to try to clarify the detailed history of the lava pile.

We thank Ole Jørgensen for samples, and Dr R. L. Fleischer, General Electric Research Laboratory, Schenectady, New York, for supplying the glass dosimeter.

#### Comb-layering in carbonatite dykes

#### Kerstin Katz & Jörg Keller

Mineralogisch-Petrographisches Institut, Universität Freiburg, FRG

Carbonatitic dykes from the Tertiary Kaiserstuhl volcano in the Upper Rhinegraben, FRG, commonly show fine-banded layering with skeletal branching calcite crystals oriented perpendicular to the layering. These calcite comb-layers are produced from magmatic in-situ crystallization in specific conditions of supercooling and rapid cooling rates 1,2. We show here that the crystallization features underline the magmatic origin of the observed textures, mineral phases and melt compositions and are a key to the physicochemical nature of the carbonatitic magma.

The term 'comb-layering' has been applied to textures in magmatic rocks characterized by layers of elongate, parallel and branching crystals with preferential orientation perpendicular to the plane of layering3. It is mostly feldspars, pyroxenes, olivine and amphibole that form the elongate crystals of comb-layers in magmatic intrusions. Moore4 found comb-layers of perovskite in olivine-melilitite and Dawson (unpublished data) observed sphene comb-layers in an ijolithe block from Oldoinyo Lengai. One example of elongate and branching calcite has been reported from a kimberlite sill at Benfontein, South Africa5. Calcite dendrites have been found in some natural carbonatites<sup>6,7</sup> and in calcite melting experiments<sup>8,9</sup>.

In general, natural examples of comb-layering have been explained as the result of crystallization from a supercooled magmatic melt. Crystallization experiments have reproduced these comb-layer textures2 and confirmed that specific conditions of supercooling, supersaturation and cooling rates are responsible for their formation.

Carbonatites in the Tertiary Kaiserstuhl alkaline complex occur as three different rock types<sup>10-12</sup>: (1) a central intrusion of coarse-grained sövite; (2) several hundred dykes cutting the subvolcanic and volcanic silicate rocks; and (3) carbonatitic lapillistones and ashes formed by the surface eruption of the carbonatite magma. The carbonatitic dykes (<1 cm to 1 m wide) exhibit a wide variety of textures from trachytoid and skeletal to porphyritic and granular. Most of the dykes consist of >90 vol.% of calcite; only a few contain larger amounts of silicate phases. Magnetite, apatite and phlogopitic mica are the main non-carbonate minerals. All dykes are alvikitic according to the nomenclature of Le Bas<sup>13</sup>.

Comb-layering parallel to the dyke margins has been observed in many of these dykes. The arrangement of layers is very regular, with a well-defined median symmetry plane and pairs of corresponding layers on either side of the centre (Figs 1, 2). The layers consist of elongate calcite crystals with a strictly parallel orientation perpendicular to the layering. Narrow dykes (maximum width 10 cm) may consist of one pair of symmetrical comb-layers only ('simply-layered dykes') (Fig. 1). Wider dykes

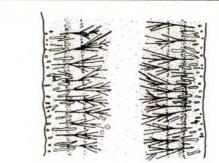

Fig. 1 a, Cross-section through simply-layered carbonatite dyke (width 5cm) with one pair of symmetrical comb-layers formed by skeletal calcite dendrites. Border vesicle zones and a fine-grained central zone are also developed. b, Micrograph of cross-section of a simply-layered carbonatite dyke with a comb-layer of columnar calcite and a granular central 'pipe' zone.

sometimes show a rhythmic banding with a succession of several comb-layers, for example Fig. 2. The layers are separated by thin bands of fine-grained carbonatite. A zone of aphyric, very fine-grained carbonatite which separates comb-layers from the actual wall-rock contact is interpreted as the chilled margin.

Single comb-layers can be up to 3 cm wide or considerably smaller (<1 mm). The elongate calcite crystals reach a length of ~2 cm with a maximum length-to-width ratio of 150:1. The elongation is perpendicular to the c-axis. Mostly the crystals are skeletal and show dendritic bifurcations (Fig. 3). The dendrites always branch towards the centre of the dykes where the elongate comb-layer calcites become closely spaced forming fanshaped bundles. A curvature of single dendritic and skeletal calcite crystals is common (Fig. 3a). The interstitial matrix between the skeletal crystals consists of granular or trachytoid calcite with extremely fine-grained (<30 µm) acicular apatite

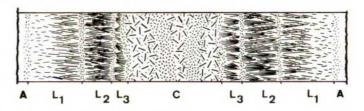

Fig. 2 Schematic cross-section through rhythmically layered comb-layer carbonatite dyke (width 25cm) A, aphyric border; L<sub>1-3</sub>, symmetrical pairs of comb-layers; C, microporphyritic to equigranular central zone.

and euhedral magnetite in varying amounts. Sometimes tiny

pyrochlore octahedra may be present.

The mineral chemistry<sup>12</sup> of calcite is rather uniform with very little variation between different dykes or single layers in one dyke. It is pure calcite with ∑MnCO<sub>3</sub>+FeCO<sub>3</sub>+MgCO<sub>3</sub>< 0.5 wt%. The SrCO<sub>3</sub> content is high and averages to 2 wt%. Apatite chemistry is characterized by high rare earth element contents (average La<sub>2</sub>O<sub>3</sub> 0.5, Ce<sub>2</sub>O<sub>3</sub> 1.0 wt%) and significant SiO<sub>2</sub> contents (up to 3.0 wt%). Low flourine concentrations (average 0.75 wt%) are in marked contrast to higher F values in apatites of the Kaiserstuhl sövites (average 2 wt%).

The granular central part between the comb-layers varies in thickness from a few millimetres in simply-layered dykes (Fig. 1) to several centimetres (Fig. 2). The contact between the centre and the comb-layer is often rather sharp. Some of the larger central zones show flow structures and in a few cases contain detached pieces of adjacent comb-layers. Vesicle zones parallel to the border occur in a few dykes. The vesicles may be void but are often filled with pure calcitic material. In the comb-layers these vesicles are elongate parallel to the dendrites. In some dykes they show a striking similarity to the carbonatitic 'migra-

tion vesicles' described by Dawson and Hawthorne5 from the kimberlite sill at Benfontein. In two dykes apatite comb-layers occur as well as the calcite ones. The apatite crystals are elongate and skeletal and branch towards the dyke centre.

Simply and rhythmically layered dykes have been chemically analysed (Table 1). Their composition shows the characteristic trace-element enrichment (for example, Sr, Ba, Nb, light rareearth elements), which is typically carbonatitic and compares well with other carbonatitic rocks of the Kaiserstuhl. There is a close chemical similarity with rapidly quenched volcanic lapilli which occur in the form of carbonatite lava droplets in the Kaiserstuhl (Table 1, no. 5). With H. W. Hubberten (unpublished data) we have studied carbon- and oxygen- isotope ratios of carbonatites from the Kaiserstuhl and analysed several comblayer zones. Their isotope ratios are within the narrow limits of primary carbonatites <sup>14,15</sup>. Values as low as -5 to -7% for  $\delta$  <sup>13</sup>C (PDB) and +5 to +8% for δ18O (SMOW) have been determined.

The conditions necessary for comb-layer formation have been discussed by Donaldson2, briefly they are: a compositional or thermal gradient causing unidirectional solidification; a degree of supercooling at which homogeneous nucleation in the melt is low and crystal growth is fast; a cooling rate that allows isotherms to advance at the same rate as the elongate crystal growth rate.

The almost monomineralic nature of the carbonatite melt reduces the importance of compositional factors on the constrained crystal growth of calcite. In this respect carbonatite magmas more closely resemble metal melts than multicomponent silicate magmas. The small, simply-layered carbonatite dykes therefore may be regarded as natural analogues of metal casts with 'columnar' wall-zones and a central 'pipe' zone (Fig. 1b). The main reason, therefore, for directed crystal growth in the narrow carbonatite dykes is supercooling in a high thermal gradient perpendicular to the dyke walls. The presence of comb-layering with elongate calcite in very narrow dykes (<1 cm) shows a high growth rate of calcite at rapid cooling. If the cooling rate exceeds the growth rate, supercooling in the

magma ahead of the solidification front will soon reach a value at which homogeneous nucleation takes place and comb-layer formation stops<sup>2</sup>. We conclude that comb-layered carbonatite dykes originated by intrusion of an almost nuclei-free melt in which heterogeneous nucleation only occurred at the dyke walls. A specific degree of supercooling maintained the low rate of homogeneous nucleation and elongate calcite crystals could grow along a thermal gradient in a rapidly cooling dyke. Experimental results 1 suggest that higher degrees of supercooling are required for comb-layer formation in melts of lower viscosity. Intrusive features of dykes and the nature of extrusive carbonatites of identical composition 11 suggest an extremely low viscosity of the carbonatite magma.

The origin of rhythmically layered carbonatite dykes is more complex. Compositional supersaturation can explain alternating comb-layers of differing mineralogy<sup>1</sup> and is suggested for the origin of the rare succession of calcite and apatite layers. Compositional supersaturation cannot be evoked for the sequence of comb-layers of very similar composition such as the calcite layers in carbonatite dykes. Periodic buildup and release of volatile pressure have been suggested as a cause for rhythmic banding<sup>1,2</sup>. This seems plausible for the shallow subvolcanic to near-surface environment in which the dykes crystallized. As comb-layer crystallization proceeds the melt becomes enriched in volatiles. This causes depression of the liquidus and stops the growth of elongate and skeletal calcite. A boundary layer is formed along which a new comb-layer starts crystallizing when appropriate supercooling conditions are re-established.

The above interpretation of banded comb-layered carbonatite dykes gives important data on the nature of the carbonatite magma. The intruding melt was almost completely liquid and dendritic calcite crystals are evidence of primary textures. Calcite was the liquidus phase in the carbonatite magma. Secondary recrystallization is of very minor importance in the present examples. The rapid cooling in narrow dykes suggests that the composition of analysed carbonatites is a good approximation to the original composition of carbonatitic melt.

This study was supported by a grant from Deutsche Forschungsgemeinschaft. We thank J. B. Dawson and C. Donaldson for valuable comments.

#### **Biologically damaging radiation** amplified by ozone depletions

#### S. A. W. Gerstl & A. Zardecki

Theoretical Division, MS 210, Los Alamos National Laboratory, Los Alamos, New Mexico 87545, USA

#### H. L. Wiser

Office of Research and Development, US Environmental Protection Agency, Washington DC 20460, USA

Many recent studies 1-3 indicate that releases of chlorofluorocarbons (CFCs)—mainly chlorofluoromethanes (CFMs)—into the atmosphere deplete the stratospheric ozone layer. Potentially dangerous consequences of these ozone depletions, such as increases in skin cancer, are expected due to a subsequent

increase in biologically damaging solar UV radiation reaching the ground. The biological effectiveness of this radiation amplification can be quantified by a radiation amplification factor (RAF) for which a value of 2 has been previously assumed: RAF = 2 means, for example, that a 1% ozone depletion will result in a 2% increase in damaging UV dose at ground level. Using accurate radiative transfer calculations together with a detailed modern data base, we calculate here the RAFs for erythemally and DNA-weighted UV-B dose assuming ozone depletions as resulting from a two-dimensional model, as well as a global ozone depletion of 10%. The amplification factor as a function of latitude and season is found to be between 1.9 and 2.2 for erythema and between 2.5 and 2.8 for DNA. This is a smaller range variation than previously claimed.

In theoretical investigations of the problem using onedimensional numerical models, the most probable value calculated for the eventual steady-state ozone depletion due to continued release of F-11 and F-12 at the 1977 level is 5-10%. New values of some of the chemical rate coefficients, such as the reaction rate of OH with HNO<sub>3</sub> (ref. 4), lead to this ozone depletion. Studies using two-dimensional models indicate that any change in ozone will not be uniform, but will show variations with latitude and season.

In estimating the resulting damaging UV dose rate (DUV) for erythemal and DNA action spectra, we consider both a globally uniform ozone depletion consistent with the predictions of one-dimensional models, and latitude/season-dependent depletions as predicted by the two-dimensional model of Pyle<sup>5</sup>. Extensive calculations of this type have already been performed during the US Climatic Impact Assessment Program (CIAP) (see ref. 7). Our new calculations use a highly efficient and versatile radiative transfer code8 in which we incorporated a detailed data base for realistic atmospheres and which allows the computation of solar irradiance spectra to a predetermined degree of accuracy. Up to 70 km altitude we consider molecular and aerosol extinction and scattering profiles and include all

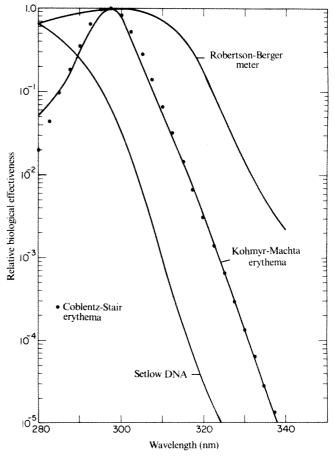

Fig. 1 Action spectra in use for biological effects of UV radiation.

orders of scattering in our computations. Our atmosphere model allows us to extend the results of Green and Mo<sup>7</sup> to larger latitudes.

We calculate first the downward solar flux at ground level for the biologically effective solar UV spectral region from 0.28 to 0.34  $\mu m$  (UV-B) for ozone depletions of 1-20%. Molecular absorption and scattering coefficients were prepared for five one-dimensional atmosphere models which correlate latitude and season9: (1) tropical; (2) midlatitude summer; (3) midlatitude winter; (4) subarctic summer; and (5) subarctic winter. Although the use of only five model atmospheres is obviously less detailed than a full two-dimensional model, this data base has proved to be adequate in extensive transmittance and radiance calculations as verified against laboratory and satellite measurements  $^{10}$ . The wavelength dependency of the ozone absorption coefficient is described by an analytical representation also used by Shettle and Green  $^{11}$ . We include absorption and scattering by aerosols which are assumed to be distributed according to a rural model profile  $^{12}$ .

The biologically damaging effect due to UV-B radiation reaching the ground may be quantified by the DUV dose rate calculated from

$$DUV = \int_{0.28 \mu m}^{0.34 \mu m} E(\lambda) I(\lambda, Z_0) d\lambda$$

where  $I(\lambda, Z_0)$  is the irradiance at ground level for the solar zenith angle  $Z_0$ , as computed from a radiative transfer calculation.  $E(\lambda)$  is the action spectrum characterizing a specific biological effect. Although changes in atmospheric ozone may produce rather small changes in the total solar flux reaching the ground, the changes in the UV-B part of the spectrum can be of considerable biological significance. The relative effectiveness of different wavelengths (the action spectrum  $E(\lambda)$ ) for most biological UV effects increases with decreasing wavelength. This function  $E(\lambda)$  must therefore be used as a weighting function for the solar irradiance when biological effects are to be estimated, as shown above for DUV. As can be seen from Fig. 1, the wavelength dependence of  $E(\lambda)$  is significantly different for biological effects<sup>2</sup>. Chemical compounds in biological systems that absorb UV-B radiation are mainly proteins and nucleic acids. For our calculations we chose as action spectrum for human sunburn the standard erythemal action spectrum<sup>13</sup> of Coblentz and Stair. The spectral sensitivity curve of the Kohmyr and Machta<sup>14</sup> modified Dobson instrument, used by Pyle and Derwent<sup>6</sup> as erythemal weighting function, is very similar to the Coblentz-Stair action spectrum, as shown in Fig. 1. As the action spectrum for human skin cancer is not known, we use the generalized DNA action spectrum compiled by Setlow11 generic representation for this damaging UV-B effect. The stronger response to shorter wavelengths of Setlow's DNA action spectrum as compared with the erythemal action spectrum leads to different results for the calculated DUV rates and RAFs. For completeness we also reproduce in Fig. 1 the spectral response curve of the Robertson-Berger meter which is used in the existing network of worldwide UV dose measurements. However, as seen from Fig. 1, and as emphasized in ref. 2, the response characteristics of this meter are quite different than the erythemal and the DNA action spectrum.

As the solar irradiance at ground level depends on the solar elevation, an effective solar zenith angle  $Z_0 = \cos^{-1} \langle \mu_0 \rangle$  is determined as a daily average over the continuously varying zenith angles at given date and latitude:

$$\langle \mu_0 \rangle = \frac{1}{T} \int_{t_{\text{sunrise}}}^{t_{\text{sunset}}} \mu_0(t) \ dt$$

where T is the duration of daylight. Figure 2 shows a plot of  $Z_0$  against latitude and season. This allows us to correlate the calculated DUV dose for a given effective zenith angle  $Z_0$ , and a given atmosphere model, with latitude and season. The consistency of using the effective solar zenith angle  $Z_0$  has been checked against the procedure in which the DUV dose is taken at several zenith angles and then averaged over the day. The

daily DUV doses as obtained by these two different averaging methods differ by <5%, which we consider adequate for this investigation.

The RAF is defined as the ratio of the percentage increase in DUV dose to the corresponding percentage decrease in total ozone. Figure 3 shows our calculated RAFs on the two-dimensional grid of latitude and season.

Considering the estimated ozone depletion in the range 1-5% through 1992 due to continued use of CFCs, as calculated by Pyle and Derwent with a two-dimensional model (Fig. 1 in ref. 6), we obtain the contour plots for the RAF of Fig. 3 when the erythemal and DNA action spectrum is used. If we consider a global ozone depletion of 10% as an estimate of a steady state condition, we obtain RAFs between 2.1 and 2.5 for erythema and between 2.8 and 3.0 for DNA. In both cases the RAFs are larger than for the lower 1992 depletion estimates which indicates the non-linearity of the radiation amplification. Note from Fig. 2 that the ratio of increase in erythemally weighted UV-B dose to the decrease in total ozone amount is always greater than unity and quite close to 2 even in the equatorial region; this is in contrast to the results reported in ref. 6. Calculations by F. M. Luther (personal communication) performed after the present analyses and extensive verifications of our computational methods and data16 indicate that the differences between our results for RAF and those of Pyle and Derwent<sup>6</sup> may be due to the different atmospheric data bases and different erythemal action spectra used in the radiative transfer calculations. The uncertainty in our results introduced by the computational method is estimated to be at most 10% in RAF for all latitudes and seasons. In addition, the radiation amplification factor for DNA-weighted DUV is close to 3 and thus significantly larger than for erythemally-weighted DUV for all latitudes and seasons. As regards the damaging effects to the human population of increased UV radiation due to continued release of CFCs, the above results may be interpreted as follows. If a 5% global depletion of ozone is reached due to the continued release of CFCs, then an amplification of biologically

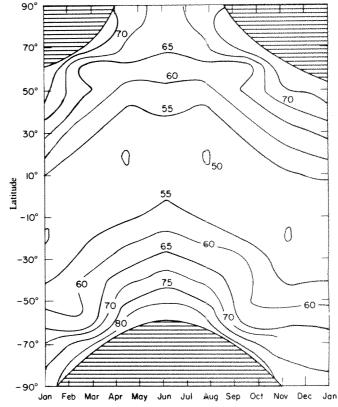

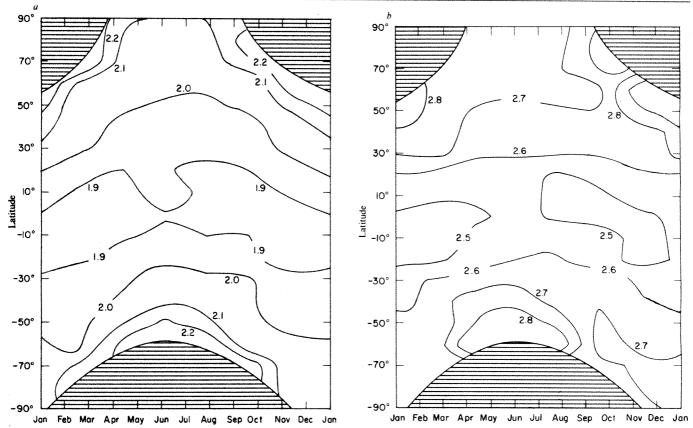

Fig. 2 Effective solar zenith angle determined as a daily average over continuously varying zenith angles at a given date and latitude. Shaded areas indicate polar regions for which no  $\langle \mu_0 \rangle$  is determined.

Radiation amplification factor for a, erythemally weighted and b, DNA weighted UV-B dose resulting from continued CFC usage through 1992. Percentage depletion in the total ozone taken after ref. 6.

damaging radiation should be expected that increases erythema ~10% (RAF ~ 2.0) and DNA damage by about 13%  $(RAF \approx 2.6)$ . The estimated increase of skin cancer rates is likely to be of the same order.

In conclusion, as our modelling indicates, the approximate value of 2 for the RAF should be replaced by a non-linear functional relationship; the larger the ozone depletion the larger the RAF. Plotted as a function of latitude and season, however, the RAF shows a fairly small gradient in all directions, consistent with the results of Green and Mo7. Using the latitude- and season-dependent ozone depletions estimated by Pyle and Derwent for continued CFC usage to the year 1992, we arrive at an RAF range between 2.5 and 2.8 for DNA-weighted UV-B dose and between 1.9 and 2.2 for erythemally-weighted dose. (These new results have been confirmed by I. Isaksen et al., unpublished data.) Note especially that our minimum RAF values are 1.9 (erythema) and 2.5 (DNA), which occur in the equatorial region.

We thank Dr E. P. Shettle for helpful discussions of atmosphere models and Dr J. Chang for making available the results of ref. 4.

#### High species diversity and abundance of the epibenthic community in an oxygen-deficient basin

#### Verena Tunnicliffe

Ocean Ecology, Institute of Ocean Sciences, PO Box 6000, Sidney, British Columbia, Canada

Oxygen-deficient basins are common features of the ocean1. Studies of the response of benthic communities to low-oxygen conditions have previously been restricted to sediment infauna, and have reported mass mortalities during sudden oxygen depletion<sup>2-4</sup> and low species diversity during sustained oxygen deficiencies<sup>5,6</sup>. The deep epibenthic fauna of a 220-m deep fjord in British Columbia experiences annual conditions of low oxygen (<1.0 ml l<sup>-1</sup>). I have observed the reactions of the attached fauna to the changing oxygen levels during numerous dives in the submersible Pisces IV over 10 months, and report here that, despite records of the decimation of benthic invertebrate populations<sup>2-5,7-9</sup>, this deep-water assemblage maintains a higher diversity and animal abundance than does much of the upper photic zone. The tolerance developed by this community for a wide range of oxygen conditions, including periods of anoxia, has interesting implications for physiology, behaviour and community evolution.

The glacier-carved fjords of British Columbia are narrow and deep and frequently have restricted water circulation; the vertical sides provide sediment-free surfaces for the settlement of epibenthic organisms. Saanich Inlet, on Vancouver Island, is such a fjord, and has a maximum depth of 220 m. For much of the year the bottom waters are anoxic and anaerobic respiration is associated with the build-up of hydrogen sulphide<sup>1,11</sup>. The oxygen deficiency is moderated by an annual flushing which brings dense, oxygenated water over the shallow sill at the mouth from the nearby Strait of Georgia<sup>12,13</sup>.

Using the manned submersible Pisces IV (Institute of Ocean Sciences, BC), it was possible to study in situ the effects of an unstable anoxic layer on a hard substratum community in this fjord. Thirty-three dives were made from May 1980 to March 1981 throughout the Saanich Inlet. At the major study site (Fig. 1) the submersible ascended close to the cliff from 215 to 30 m. Water samples were collected in situ within 2 m of the cliff by a sampling system on the submersible and later analysed for dissolved oxygen. By extending the sampling tube, oxygen values at 0.05 m and 2 m off the rock face could be compared; no significant differences were found.

Photographs of the cliff were taken at 5-m intervals in depth using an external strobe light and an internal camera placed 1 m from a 30×30-cm quadrat extended from the submersible to touch the rock. The distributions and abundances of animals larger than 1 cm were determined for each photograph and the diversity calculated from the combined results. Species identifications were made from close-up photographs and verified from collections of loose rocks.

The dissolved oxygen structure for the sampling period is plotted in Fig. 2. Until late August 1980, the bottom 55 m of Saanich Inlet were anoxic. Dense, oxygenated water downwelled into the bottom layers and pushed a wedge of anoxic water upwards throughout September. In late October, the epibenthic fauna as shallow as 85 m was exposed to water with <0.1 ml  $O_2$  per l. Re-oxygenation ceased after November and by May 1981 the bottom waters developed patches of anoxia.

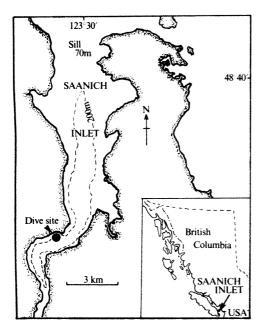

Fig. 1 Location of submersible dive site in Saanich Inlet, British Columbia. Deep-water circulation is restricted by the sill at the mouth of the inlet. In the south the walls are nearly vertical, exposing a silt-free gneissic substratum. Typical summer salinities range from 28.5% at the surface to 31.2% at 200 m; freshwater run-off into the inlet is minimal, the greatest influence being from the Cowichan River north of the sill from which intrusions into the inlet can be measured 13. Suspended sediment load is correspondingly low, although dense turbid layers due to plankton may form 13. Tidally influenced currents result in shallow-water exchange over the sill 17 and these daily fluctuations are detectable in the middle of the inlet but at velocities that rarely exceed 10 cm s<sup>-1</sup> (data not shown). The euphotic zone, defined by light levels >1% of that at the surface, was <20 m in the spring.

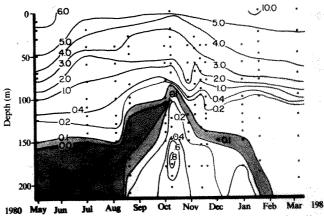

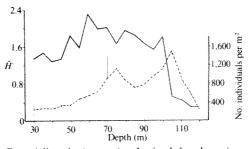

Fig. 2 Dissolved oxygen contours in ml O<sub>2</sub> per 1 for Squally Reach, Saanich Inlet, British Columbia. Sample points represent water drawn both by surface casts and by Pisces IV submersible; in the latter case, samples were fixed immediately inside the submersible and later analysed by the modified Winkler technique. Shading indicates anoxic zone. The disruption of contours from September to November 1980 is due to deep-water renewal by dense, oxygenated water entering the inlet over the sill.

Photographs and examination of samples in May 1980 showed the rock from the bottom to 130 m to be bare of macroscopic life. Small white sponges (Suberites simplex) appeared at 130 m and galatheid crabs (Munida quadrispina) at 127 m. In October, the anoxic layer was located between 100 and 130 m (Fig. 2). Tube worms were contracted, brachiopods closed and anemones limp. Dense populations of crab were found at 85 m (B. Burd, personal communication) where they had retreated as the anoxic water rose. By November brachiopod shells and crab carapaces were seen on ledges below 100 m; a few encrusting sponges were disintegrating and fragments of ascidean tunics were present between 85 and 100 m. Despite these observations, comparison of photographs taken above 120 m before and after the anoxic rise detected no significant changes in abundance of non-motile fauna. However, no epifauna were observable from the submersible between 130 and 120 m.

Two peaks in animal abundance (Fig. 3) were observed at 100 m and 75 m. At the lower depth, 84% of the individuals were sponges; at 75 m, 75% were ascideans. Numbers steadily declined towards the top station at 30 m and cover was correspondingly low. Above 30 m a distinct algae-dominated shallow-water fauna was present.

Diversity (Fig. 3) between 85 and 100 m was surprisingly great in view of the prevailing low-oxygen conditions. At 60 m it

**Fig. 3** Faunal diversity (----) and animal abundance (----) as measured from photographs from the submersible.

$$\hat{H}' = \sum_{i=1}^{n} p_i \ln p_i$$

(Shannon-Weaver diversity index)<sup>18</sup>. Four photographs were used for each depth from submersible ascents on the same location in September and November 1980, and February and late March 1981; qualitative comparisons were made with photographs taken without the quadrat in May 1980. Pictures were taken only where the rock was within 15° of vertical and the submersible could manoeuvre close to the rock. The resulting photographs of the 30×30-cm quadrat were readily reproduced to life size and so analysed for animals larger than 1 cm.

Fig. 4 Photograph from Pisces IV at -85 m. Here, the epifauna is dominated by ascideans but brachiopods, sponges and hydroids can also be seen.

marked the point at which animals of both shallow-water and high-oxygen dependence overlapped with the deeper, more tolerant species. In the photic zone diversity dropped with the appearance of encrusting red algae at 50 m. More than 40 species of epibenthic animals were identifiable from the submersible between 120 and 85 m and many more from rock samples. Phyletic diversity was high in this zone; 10 phyla were represented, including 16 classes. Conversely, infaunal assemblages of oxygen-poor areas were mostly impoverished5-

The oxygen levels at which the greatest faunistic changes are reported to occur are 1.5 and 1.0 ml l-1 (refs 6, 9). Despite < 1.0 ml l<sup>-1</sup> of oxygen for half the monitored time, the zone between 85 and 100 m had neither low diversity nor small populations (Fig. 4); even shelled animals such as brachiopods were common, despite possible physiological dissolution of carbonate6

The flushing of Saanich Inlet and the rise of anoxic water is an annual event  $^{1.13,14}$ ; 0.5 ml  $O_2$  per l has been recorded as shallow as 60 m. Elsewhere, similar influxes of low-oxygen water have resulted in the demise of large areas of benthic fauna<sup>3,4,7</sup>. Either a benthic community repeatedly re-establishes itself after oxygen deficiency<sup>5,7</sup> or it becomes highly tolerant of changing oxygen conditions. The latter seems to be the case in Saanich Inlet; the community maintained a stable constituency, noticeable mortality occurred only in areas of sustained anoxia and throughout the 10 months, there was no significant recruitment to any taxon.

The persistence of this community is pertinent to (1) the behavioural and physiological adaptations that allow survival in very low-oxygen conditions; (2) the possible regulation of competitive dominance 10,15 in the substrate-limited depths by periods of anoxia that cause some mortality; and (3) the evolution of community structure during the Palaeozoic when atmospheric levels of oxygen were low 16—the composition and behaviour of the deeper part of this community may reflect patterns in early Cambrian assemblages.

Without the continued support of the crew of Pisces IV, this work would not be possible. I thank B. Burd, Dr R. Brinkhurst and, especially, G. Calderwood.

#### Epithelial cells of Hydra are dye-coupled

#### Scott E. Fraser\* & Hans R. Bode†

\* Department of Physiology and Biophysics and † Department of Developmental and Cell Biology and the Developmental Biology Center, University of California, Irvine, California 92717, USA

In the past decade, a strong correlation has been established between gap junctions, seen in cell ultrastructure studies, and cell coupling (ionic, metabolic or dye coupling) assayed physiologically1. In Hydra, ultrastructural analyses have indicated that the epithelial cells of both cell layers are connected extensively by gap junctions; gap junctions have also been observed between the two layers<sup>2-7</sup>. On the basis of these results, one would expect electrical and dye coupling between epithelial cells of Hydra. However, de Laat et al.8 reported that these cells were neither dye- nor electrically coupled, which was unexpected as cells in another coelenterate have been shown to be coupled ionically9. Cell-cell coupling in Hydra is particularly interesting because extensive experiments on head regeneration in this coelenterate have led to well-defined models of patterning that require communication between cells of the type that may be provided by gap junctions 10-14. We have re-examined dye coupling in Hydra and we report here that, after injection of Lucifer yellow into single epithelial cells, neighbouring cells were observed to contain the dye. We conclude that the epithelial of cells of Hydra are indeed dye-coupled.

The body column of Hydra consists of two layers of epithelial cells, the epidermis and the gastrodermis, arranged in a cylindrical shell with the epidermis on the outside and the gastrodermis lining the gastric cavity. The cells of both layers possess large vacuoles; results of light and electron microscopy studies suggest that these vacuoles occupy less than half the cell volume <sup>15,16</sup>. By fixing the animals in isotonic solutions instead of the typical hypertonic solutions, it has been shown (R. D. Campbell, personal communication) that the vacuole actually comprises a much greater fraction (perhaps 80-90%) of the cell volume. The cytoplasm is therefore often only a thin shell 1-3 µm thick between the plasma membrane and the vacuoleelectrophysiological properties support this arrangement. On penetrating an ectodermal epithelial cell with a glass microelectrode, several investigators have found a transient negative membrane potential, followed by a stable positive potential 17-1 Chain 19 reported that the electrode could then be moved large distances into the cell without altering the positive potential, consistent with the electrode being within the vacuole. Movement of the animal has also hindered intracellular electrophysiological investigations of *Hydra*. During impalement, movement of only a few cell diameters is sufficient to interfere with measurements. Impaling an otherwise quiet *Hydra* can induce movement, and use of nerve-free *Hydra*<sup>20,21</sup>, which are not moving on a macroscopic scale, is of little help as they still make small movements. Thus the delicate process of penetrating and remaining in the thin shell of cytoplasm is made even more difficult.

To increase the likelihood of positioning the electrode in the cytoplasm of the cell, we used the following techniques. Movement of *Hydra* was eliminated by: (1) Removing the head and foot of the animal, which greatly reduced stretching and contraction of the body column. (2) The body column was threaded onto monofilament fishing line having a diameter slightly larger than that of the body column. The column easily stretched circumferentially to accomodate the larger diameter. (This is a standard technique used in *Hydra* grafting experiments <sup>13,14,22,23</sup>.) (3) Animals were starved for 2–4 days (*Hydra* can starve for 10–15 days and still remain healthy). To reduce vacuole size, animals were acclimatized to 50 mM sucrose in *Hydra* medium for 18–24 h, which does not affect the health of the animal <sup>18</sup>. With these treatments, stable negative or positive membrane potentials were readily obtained.

Epithelial cells were impaled with micropipettes containing Lucifer yellow and filled with the dye iontophoretically. While developing methods to optimize cell impalement, we observed that the cells are coupled in a wide variety of conditions (normal, sucrose and hypertonic medium), which indicates that coupling of the cells is not an abnormal state induced by our manipulation of the conditions. Of the 121 cells that were impaled, 44 were located by fluorescence microscopy; for 19 of these, Lucifer yellow was found in at least one neighbouring cell. Presumably, a large number of cells could not be found due to cell death.

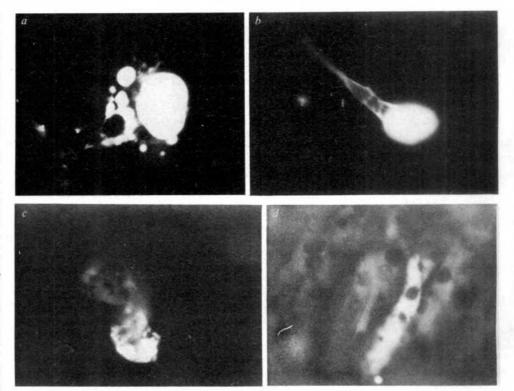

Occasionally, cells lysed while being observed in the fluorescence microscope. No residual dye remained after such lysis and the neighbouring cells did not pick up any dye.

In subsequent experiments using the improved methods described above, 86 cells were impaled and filled with Lucifer yellow: 45 of these were located by fluorescence microscopy, and 25/45 cases demonstrated passage of the dye to one or more neighbouring cells. Four examples of dye-injected cells are shown in Fig. 1. In all cases, the filled cells were epithelial cells, as opposed to the much smaller cells found in the interstices between epithelial cells. They were of the same size and shape as epithelial cells and often had long processes extending away from the cell, which were probably muscle processes found at the base of each epithelial cell type<sup>24</sup> (see Fig. 1b).

Two distinct patterns of dye distribution were observed. In one, the cytoplasm was uniformly, intensely stained, while several round dark spots (assumed to be vacuoles and the nucleus) were not (Fig. 1d). In the other pattern, one of the vacuoles was very intensely stained while the remainder were not. In these cells, the cytoplasm was much less intensely stained (Fig. 1a, b). Although no dye passage was seen in these cases (Fig. 1a, b), dye coupling was observed for both types of filled cell (Fig. 1c, d). The vacuoles of the cells coupled to the injected cell were always dark compared with the cytoplasm. Coupling was observed both within each cell layer and between cell layers.

Two types of membrane potential were also found. In some cases, the membrane potential was negative  $-10\pm 6\,\mathrm{mV}$  ( $\pm$  s.d.) before, during and after filling the cell with Lucifer yellow. In other cases, a positive membrane potential was obtained ( $+21\pm 8\,\mathrm{mV}$ ) before, during and after dye filling. Occasionally, the initial potential was negative, and suddenly switched to positive during dye filling. The reverse switch was never observed. These potentials are probably not an exact measure of the

Fig. 1 Sample micrographs of Hydra cells filled with Lucifer vellow. a, b, A region with positive membrane potential was filled with the dye and no passage occurred. In a, there was no leakage of dye from the vacuoles; in b, the cytoplasm was clearly labelled as well as the single bright vacuole. Presence of Lucifer yellow in the cytoplasm was always easily recognized by the fine cell processes that were filled with the dye. The vacuole in a fragmented into many smaller vacuoles during observation, before the photograph was taken. c, Dye passage in a region of positive membrane potential which was dye filled. A bright apical vacuole was observed in the cell, with considerable amounts of dye in the surrounding cytoplasm. The dye passed to two cells, one of which is in the plane of focus. d, A region of negative membrane potential that was dye filled. The vacuoles in all these cells were dark. The dye passed to many other cells, extending beyond the limits of the photograph. The cell shape observed in a-d varies because the shape of the animals at the time of observation. Cells were identified (epidermis as opposed to gastrodermis) by their plane of focus with respect to the mounted stenoteles, which are know to be on the outer surface of Hydra 30. Hydra attenuata were maintained in Hydra medium (1 mM CaCl<sub>2</sub>, 1 mM NaHCO<sub>3</sub>, 10 µM EDTA), and were starved for 2-4 days before an experiment. For the 18-24 h preceding an

experiment, the medium was supplemented with 50 mM sucrose (to reduce vacuole size). The head and basal disk of the animal were removed and the resulting body column threaded on to a monofilament fishing line (0.25 mm diameter). The fishing line was secured with dental wax in the centre of a Petri dish filled with sucrose–Hydra medium (with body column parallel to the dish bottom). The dish was mounted on the stage of a Hoffman modulation microscope (viewed at ×280); illumination was supplied by a fibre optic light source placed outside the Faraday cage, with heat filters and a red filter positioned in the light path to avoid damaging the Lucifer yellow-filled cells. Glass micropipettes (200–800 Ω) were pulled from Ultratip glass (Haer) and black-filled with 3% Lucifer yellow CH (Aldrich). Cells were impaled using a piezoelectric bending element which withdrew the electrode slightly (2 μm) and then allowed it to snap forward, thus penetrating the cell membrane. Lucifer yellow was introduced into the cell iontophoretically with 0.5 nA hyperpolarizing current pulses (1 Hz, 50% duty cycle) for 15 s. The animals were removed from the fishing line and allowed to recover in the dark for 10–60 min, after which time they were pressed between two microscope coverglasses in a small amount of sucrose–Hydra medium. A small bead of silicone grease (Dow-Corning) placed between the two coverglasses prevented the animals from being overly flattened. This 'sandwich' arrangement could be flipped to view both sides of the animal. The animals were observed and photographed (×325) with a Zeiss UEM epifluorescence microscope through a Zeiss filter set designed for Lucifer fluorescence (487704).

Table 1 Correlation between membrane potentials and staining patterns of Hydra epithelial cells

***************************************			
Staining pattern	Type of membrane $-/ (n = 38)$	,	(initial/final) +/+ (n = 38)
Cells that could be located	7	9	29
a, Bright cytoplasm and dark vacuoles	7	2	5
No. of cells coupled	4	1	3
b, Bright vacuole and dim cytoplasm	0	7	21
No. of cells coupled	-	4	10
c, Ambiguous No. of cells coupled	0	0	3 2

Data from the final set of animals in which the membrane potential was measured before, during and after the injection of Lucifer vellow. The cells were grouped together by the membrane potentials before and after injection. Techniques used are described in Fig. 1 legend. The cytoplasm of all five samples with positive, positive potentials (+/+)and one with negative, positive potentials (-/+) in a were much less intensely stained. This low level of observed dye could be due to dye passage from a filled cell which subsequently lysed, accounting for the cytoplasmic dye location. In three of these six cases, fluorescent debris was observed around the dimly fluorescent cells.

membrane potential because the size of the electrode tip potential is unknown. A contribution from the tip potential could be substantial due to the large difference between the ionic strength of Hydra medium (5 mM) and that of the cytoplasm (120-150 mM) (ref. 25 and H.R.B., unpublished results). Nevertheless, two distinct cell regions of differing membrane potential were consistently observed throughout our experiments.

A correlation was observed between the staining patterns and membrane potentials (see Table 1): intensely stained vacuoles and dimly labelled cytoplasm were correlated with positive potentials. These results are consistent with the positive potential resulting from penetrating a vacuole. The appearance of dim fluorescence in the cytoplasm of the positive potential fills indicated that some leakage of the dye occurred during and/or after dye filling, perhaps when the electrode was withdrawn. Although there were equal numbers of cells filled with dye for each type of membrane potential, a much smaller fraction (18% as opposed to 76%) of the 'negative, negative' fills were later located, suggesting a higher probability of cell damage when impaling the cytoplasm.

It seems likely that in previous work8, which recorded positive membrane potentials for many of the cells impaled, the electrode was placed in the vacuole, as we found a strong correlation between positive potentials and dye filling of the vacuole. This may have greatly reduced the chance of observing ionic or dye coupling. In addition, cell damage or cell death may have uncoupled the cells. Approximately half the cells that were successfully filled with dye in our work showed no dye passage, which we take to indicate the ease with which the cells may be damaged.

Our results clearly indicate that the epithelial cells of Hydra are dye-coupled, probably through gap junctions, as has been well established in the epithelia of other animals. This finding is of particular interest in Hydra in terms of pattern formation. Two developmental gradients, one of activation and one of inhibition, are involved in the formation of the head at the apical end<sup>8,10,14,26</sup>, and a further two gradients control foot formation<sup>10,13,14</sup>. Indirect evidence suggests that the inhibition gradients are due to diffusible substances<sup>13,27,28</sup>. Recently, it has been shown that the epithelial cells are responsible for transmission of the head inhibition down the body column<sup>29</sup>. A logical channel for the movement of such a diffusible substance would be through the gap junctions of the epithelial cells.

We thank Dr M. Bronner-Fraser and P. Bode for critical reading of the manuscript. This work was supported by grants Hd08086 and GM29130 and NSF grant BNS-8023638.

#### Protein phosphatase-1 is involved in Xenopus oocyte maturation

#### Denise Huchon\*, René Ozon\* & Jacques G. Demaille†‡

Laboratoire de Physiologie de la Reproduction, Groupe Stéroides, ERA CNRS 964, Université Pierre et Marie Curie, 4 Place Jussieu, 75230 Paris Cédex 05. France

† Centre de Recherches de Biochimie Macromoléculaire du CNRS. Faculté de Médecine and U-249 INSERM Biochimie des Régulations des Systèmes Contractiles, BP 5015, 34033 Montpellier, France

Two key steps in meiotic maturation of the Xenopus oocyte involve protein phosphorylation-dephosphorylation<sup>1</sup>. A burst of cyclic AMP-independent phosphorylation occurs at the time of the breakdown of the nuclear envelope, whether maturation is triggered by progesterone, by the inhibitor of cyclic AMP-dependent protein kinase (PKI)<sup>2</sup> or by the maturation promoting factor (MPF)<sup>1,3</sup>. Also, an *in ovo* decrease in the level of the free catalytic (C) subunit of cyclic AMP-dependent protein kinase, induced by microinjection of pure PKI<sup>4</sup>, initiates meiotic maturation<sup>1,2,4</sup>. This suggests that MPF appears only after dephosphorylation of a phosphorylated maturation protein Mp-P<sup>4</sup>. We now show, by microinjection of pure inhibitor-1 of protein phosphatase-1<sup>5</sup>, which blocks progesterone- and PKI-induced maturation but not the MPFinduced one, that protein phosphatase-1 catalyses the dephosphorylation of Mp-P.

Phosphoinhibitor-1 was injected into Xenopus oocytes to a final concentration of 15 µM. Microinjected oocytes maintained in saline remained morphologically healthy and resumption of meiosis never occurred. When exposed to  $1 \mu M$  progesterone 4 h after microinjection of inhibitor-1, they matured with the same efficiency and kinetics as controls, showing that inhibitor-1 is neither an inducer of maturation by itself nor toxic to the cell. Oocytes were also stimulated by 1 µM progesterone at various times before and after the microinjections (Fig. 1). Inhibitor-1 proved to be a potent inhibitor of maturation, having maximal efficacy when injected 1 h after incubation with the steroid. In contrast, microinjection of inhibitor-1 3 h after progesterone

<sup>‡</sup> To whom correspondence should be addressed

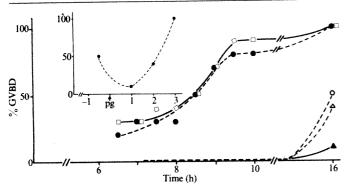

Fig. 1 Comparison of kinetics and % maturation after treatment with progesterone and phosphatase inhibitor-1. Ten oocytes were exposed either to 1 μM progesterone only (•) or to 1 μM progesterone 30 min after (○), 1 h before (△), 2 h before (△) or 3 h before ( ) inhibitor microinjection. Inset shows the time dependence of inhibitor efficacy: % of germinal vesicle breakdown (GVBD) 16 h after exposure to progesterone (pg) versus time of microinjection. Fully grown oocytes (stage VI11) were defolliculated as described elsewhere<sup>4</sup>. Inhibitor-1 of phosphoprotein phosphatase-1 was purified according to Nimmo and Cohen<sup>5</sup> and phosphorylated<sup>9</sup> by the pure catalytic subunit of cyclic AMP-dependent protein kinase 12. Phosphoinhibitor-1 was freed from the catalytic subunit and MgATP by heat treatment and dialysis with 60 mM ammonium bicarbonate, lyophilized and dissolved in a 5 mM MES (2(N-morpholino) ethane sulphonate) buffer pH 7.0, containing 1 mg of serum albumin per ml. Microinjection at the equator level of 50 nl of a 100  $\mu M$  solution yielded an intracellular concentration of 15  $\mu$ M, assuming a diffusion compartment of 0.3  $\mu$ l (ref. 4). As inhibitor-1 was calculated to be 1.5 µM in skeletal muscle<sup>5</sup>, microinjected inhibitor-1 should block all protein phosphatase-1 present. Its dephosphorylation into the inactive dephospho form is indeed prevented by the high free C subunit level of the resting oocyte4. The criterion for maturation was the appearance of a white spot at the animal pole of the oocyte. This experiment was done using oocytes from the same female; similar results were obtained with oocytes from two other females.

stimulation failed to alter the rate and extent of maturation, suggesting that inhibitor-1 blocks the steroid-induced maturation at an early step, without interfering with the effects of MPF. Indeed, microinjection of MPF into oocytes already injected with inhibitor-1 induced normal maturation (Fig. 2). The site of action of inhibitor-1 in the events triggered by progesterone was more precisely delineated by inducing maturation with pure PKI4. Inhibitor-1 inhibited the effect of subthreshold doses of PKI (≤0.3 µM) while maturation induced by higher PKI concentration was only delayed (Fig. 3).

These findings confirm the four-step scheme of meiotic maturation proposed previously4: on reassociation of regulatory and catalytic subunits of cyclic AMP-dependent protein kinases, resulting from the progesterone-induced fall in the cyclic AMP levels, a phosphorylated maturation protein Mp-P is dephosphorylated to the active form Mp, which triggers the synthesis of

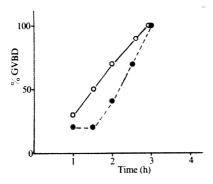

Fig. 2 Comparison of kinetics and % maturation after microinjections of phosphatase inhibitor-1 and MPF. Ten oocytes were injected either with MPF ( ) or with inhibitor-1 and then immediately with MPF (O).

MPF. If this scheme were correct, progesterone- and PKIinduced maturation, but not the MPF-induced one, should be blocked by phosphatase inhibitors, as shown here to be the case. The efficacy of inhibitor-1 shows that the putative Mp-P is a substrate of its specific target, protein phosphatase-1, and that a type-2 phosphatase cannot be the major enzyme involved in Mp-P dephosphorylation<sup>6</sup>. This confirms previous reports of protein phosphatase-1 in a number of tissues and its catalysis of the dephosphorylation of various substrates belonging to different metabolic pathways7. It also eliminates initiation factor eIF-2 from this step in maturation because eIF-2 phosphatase was recently shown to be a type-2 phosphatase8. However, the remote possibility that inhibitor-1 blocks maturation by an unknown indirect mechanism cannot be excluded, even though protein phosphatase-1 is the only known target of inhibitor-1.

The fact that inhibitor-1 is more efficient when injected 1 h, rather than 2 h after the exposure to the steroid, indicates a slow, rate-limiting dephosphorylation of Mp-P into Mp, resulting from the balance between reduced protein kinase activity and a phosphatase activity that is either constant or enhanced by the dephosphorylation of endogenous inhibitor-1.

That oocytes escape at least in part the inhibitor-1-induced maturation blockade after a prolonged time is readily understood from the fact that inhibitor-1 does not inhibit its own

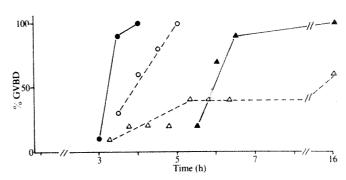

Fig. 3 Comparison of kinetics and % maturation after phosphatase inhibitor-1 and PKI treatment. PKI was microinjected 1 h after microinjection of inhibitor-1. Ten oocytes were injected either with 15 µM inhibitor-1 and 1.5 µM PKI (○) or with 15 µM inhibitor-1 and 0.3 µM PKI (△) or with 1.5 µM PKI (●) or with 0.3 µM PKI (▲). This experiment was done using oocytes from the same female; similar results were obtained with oocytes from two other females. PKI was prepared and injected as described previously<sup>4,13</sup>.

dephosphorylation by protein phosphatase-19. Microinjection of high concentrations of PKI only delays maturation because the total inhibition of the catalytic subunit of cyclic AMPdependent protein kinase leads to rapid inactivation of inhibitor-1 by protein phosphatase-1 which dephosphorylates the inhibitor into its inactive dephospho form10

This work also raises the intriguing possibility that inhibitor-1 is the maturation protein per se, although there is no experimental evidence for such identification.

The research was supported by DGRST, INSERM, CNRS and Fondation pour la Recherche Médicale.

## Perivascular infiltrates of leukocytes in brains of scrapie-infected mice

#### C. Museteanu & H. Diringer

Robert Koch-Institut des Bundesgesundheitsamtes, Nordufer 20, D-1000 Berlin 65, FRG

Four chronic subacute spongiform encephalopathies—Kuru and Creutzfeld-Jakob diseases of man, transmissible encephalopathy in mink and scrapie in sheep—are caused by slow viruses with unconventional biological and biochemical properties<sup>1-4</sup>. Since the transmission of the scrapie agent to mice<sup>5</sup> and the comparative histological analysis of Kuru in man<sup>6</sup> and of scrapie in the mouse, scrapie-mouse systems have become important models of spongiform encephalopathies. The predominant histopathological lesions (for review see refs 2, 4) found in these diseases result from nerve cell degeneration<sup>7</sup>. It seems that, in contrast to diseases of the nervous system caused by conventional viruses, perivascular leukocyte infiltrations do not play any part in the progression of spongiform encephalopathies and it is not known whether leukocyte infiltrations can be induced by unconventional slow viruses. Here we report that scrapie infection can indeed produce such lesions in mice.

Perivascular cuffs have occasionally been found in brains of patients with Kuru<sup>1,2</sup>, but there are conflicting data on scrapie. Perivascular cuffs have been reported to be absent from histological sections of brains from scrapie-diseased animals, but present in intracerebrally (i.c.) injected scrapie- and mockinfected goats, and in brains of sheep injected i.c. with scrapie agent<sup>10</sup>. However, no controls were used in the latter study. Zlotnik and Rennie<sup>11</sup> observed similar lesions in naturally infected sheep but also in control animals which were apparently healthy. Therefore, they did not consider these lesions to be associated with the disease.

We first studied scrapie in inbred STU mice<sup>12</sup> using mouse brain containing Chandler agent (47th passage; from Dr R. Kimberlin). When injected i.c.<sup>13</sup> and passaged in our mice, this material gives incubation periods of ~150 (10<sup>-2</sup> dilution of brain) to 240 (10<sup>-7</sup> dilution) days. Examination of haematoxylin-eosin-stained sections of brains from mice infected i.c. with scrapie material revealed perivascular cuffs in some sections of a

few animals at the clinical stage of the disease (Fig. 1a). We found these lesions only when the whole brain was sliced and five 10- $\mu$ m sections taken every 200  $\mu$ m. We therefore used this technique to analyse brains of age-matched, mock-infected and scrapie-infected animals for perivascular cuffs. Aliquots (50  $\mu$ l) of a  $10^{-2}$ - $10^{-3}$  dilution of brains from scrapie-diseased or healthy mice were injected intraperitoneally (i.p.), to avoid any possible immune reaction to brain injury. The mice developed symptoms of clinical scrapie 170-200 days after infection.

In the first experiment, only animals infected with scrapic material were used and histology showed that 5/10 developed perivascular cuffs (Table 1). Four animals were scored as positive in the advanced incubation period of the disease, at days 150–192. Surprisingly, however, one animal was scored as positive at day 73 after infection when less than one-half of the incubation period had passed and clinical and histological diagnosis of scrapic was not possible. However, titres of the scrapic agent have been reported at this stage for Compton white mice<sup>14</sup>.

In experiment 2, coded brains of control and infected mice were examined 'blind'—without the histologist knowing the number of infected brains; 4 of 14 brains of scrapie-infected animals were scored as positive whereas no control animals showed perivascular cuffs. Again, in one mouse brain infiltrates were detected in the early phase of the incubation period, at day 63.

Experiment 3 examined only advanced cases of scrapie, with the result that even in severely sick animals, only a limited number of mice (4/10) showed lesions. However, note that our technique of serial sectioning allowed histological examination of only one-fifth of the total brain. Control animals were free of infiltrations.

We have no evidence that the perivascular cuffs observed could be related to a possible contagious agent in the mouse stock as: (1) STU mice are no more susceptible to infections than conventional inbred mouse strains: (2) infected and mockinfected animals were kept in the same room; and (3) the experiments were performed at different times as indicated in Table 1. (4) No mice died during the experiment and none looked sick before clinical symptoms of scrapie appeared. (5) In experiments 2 and 3, the spleens were removed and the weights of single spleens recorded. There was no indication of a splenomegaly related to the perivascular cuffs.

Because of the long incubation period, even after i.c. injection, and as perivascular cuffs also developed in an animal

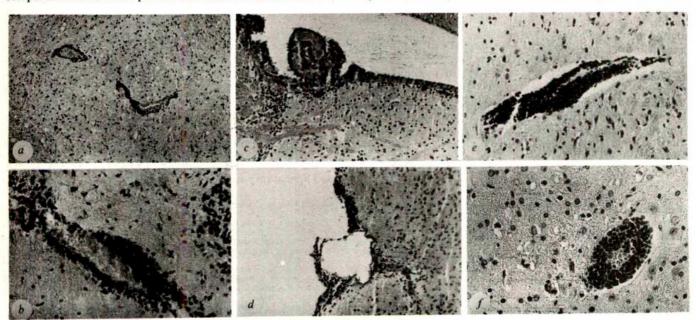

Fig. 1 Examples of meningeal leukocyte infiltrations and perivascular cuffs in scrapie-infected mouse brains. a, Perivascular cuffs 138 days after i.e. injection (×58); and b, 63 days after i.p. injection (×133). c, Meningeal infiltration 73 days after i.p. injection (×85); and d, 147 days after i.p. injection (×85). e, Perivascular cuffs 163 days after i.p. injection (×133); and f, 204 days after i.p. injection (×217).

**Table 1** Leukocyte infiltrations in mouse brain after i.p. injection of  $10^{-2}$ – $10^{-3}$  dilutions of brain material from healthy or scrapie-diseased mice

	No. of animals injected		Days post-injection on which animals were killed for	No. of animals with leukocyte infiltrations	
Expt	Control	Scrapie	histology	Control	Scrapie
1 (1979)		10	25, 56, 73(+), 120, 132, 150(+), 170(2)(+), 178(+) 192(+)	,	5/10
2 (1980)	21	14	20, 35, 42, 56, 63(+), 70, 77, 91, 105, 119, 133, 147(+), 161(+), 176(+)	0/21	4/14
3 (1980)	4	14	190, 204	0/4	4/14
4 (1981)	12*	12*	65(12), 71(+)(12)	0/12	2/12

Numbers in parentheses in column 4 indicate numbers of animals taken for histology. Animals in which perivascular cuffs were found are indicated by (+). All histology was done using coded material.

Animals received brain material treated with formalin

which received an i.c. inoculum of a 10<sup>-7</sup> dilution of scrapie brain material, it is unlikely that our passaged material could have been contaminated by another contagious agent. Nevertheless, we tried to exclude this possibility by exploiting the high degree of resistance of the scrapie agent to formaldehyde15 To destroy any other infectious agents, a low speed (500g for 5 min) supernatant of a 10<sup>-1</sup> brain homogenate was pretreated with 8% formalin at room temperature for 16 h and then injected  $(10^{-3} \text{ dilution})$  into mice. As in experiment 2, coded brains were scored for perivascular cuffs 65 and 71 days after infection, when diagnosis of scrapie was not possible. All controls were free of perivascular cuffs, whereas 2/12 animals of the group which had received scrapie-infected material were positive. Examples of leukocyte infiltrations at various times after i.p. injection are shown in Fig. 1; we have selected mild (Fig. 1c, d) and more severe (b, e, f) infiltrations to indicate the range of our scoring. Perivascular cuffs have been observed mainly in the hippocampus and thalamus at very low frequency during the routine examination of many thousands of brains of several mouse strains infected with various different strains of scrapie (H. Fraser, personal communication).

Our results thus show that leukocyte infiltrations can be induced by an unconventional slow virus and that brains of healthy animals are free from these lesions; that in some cases perivascular cuffs can be detected relatively early in the latent period, when diagnosis of the disease is not possible, but that they do not occur in all infected animals, even in the clinical phase when the disease can be diagnosed by symptoms and histology. Thus it is possible that the apparently healthy control sheep observed by Zlotnik and Rennie<sup>11</sup> to contain perivascular cuffs but showing no clinical symptoms were animals harbouring the scrapie agent. Although our technique could not detect perivascular cuffs in all scrapie-infected animals, we suggest that these lesions are not incidentally associated with the disease but may be a consequence of a very weak virus-induced autoimmune response, as has been reported for Kuru and Creutzfeld-Jacob diseases<sup>17</sup>. However, it is also possible that the perivascular cuffs are caused by an immune reaction to a product of the scrapie agent which has extremely low antigenicity. Furthermore, our results indicate that this may also be the case for diseases of the central nervous system in man, in which perivascular cuffs are seen occasionally, but which are not known to be caused by an infectious agent.

#### Immunization against blood-stage rodent malaria using purified parasite antigens

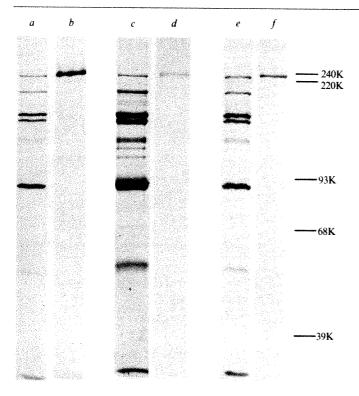

#### Anthony A. Holder & Robert R. Freeman

Department of Immunochemistry, The Wellcome Research Laboratories, Langley Court, Beckenham. Kent BR3 3BS, UK

We have reported the production of several hybridoma lines secreting monoclonal antibodies recognizing antigens of the blood forms of a rodent malaria parasite, Plasmodium yoelii yoelii<sup>1,2</sup>. Line WIC 25.77 secretes an IgG2a (antibody 25.77) which reacts specifically with merozoites in the indirect immunofluorescence (IIF) assay, and which was protective on passive transfer. Another of the hybridoma lines, WIC 25.1, secretes an IgG2a (antibody 25.1) which reacts with an antigen apparently associated with the membranes of schizonts, but this antibody was not protective on passive transfer. We have used our monoclonal antibodies to identify and purify antigens of P. y. yoelii, and we report here that mice immunized with either a 235,000 apparent molecular weight (MW) merozoite-specific protein or a 230,000 MW schizont protein and its proteolytic derivatives were protected against infection with P. y. yoelii.

Schizonts were obtained by centrifugation of P. y. yoeliiinfected mouse erythrocytes through a layer of Histopaque, and were metabolically labelled in vitro with 35S-methionine. The labelled schizonts (including a subpopulation of segmenters containing mature merozoites) were solubilized in a buffer containing a nonionic detergent. Immunoprecipitation of the extract followed by SDS-polyacrylamide gel electrophoresis (SDS-PAGE) of the washed immune complexes and fluorography revealed that antibody 25.77 reacted with a single polypeptide of 235,000 MW whereas antibody 25.1 precipitated eight major polypeptides and several minor bands (Fig. 1a, b). The apparent MWs of the major polypeptides were estimated to be 230,000, 197,000, 160,000, 151,000, 126,000, 90,000, 56,000, and 28,000.

Preparative scale purification of these antigens was achieved by monoclonal antibody affinity chromatography. Washed y. yoelii-parasitized mouse erythrocytes were extracted in a buffer containing 1% (v/v) NP40 and protease inhibitors. After high speed centrifugation the supernatant was applied sequentially to two columns containing 25.77 antibody-Sepharose and 25.1 antibody-Sepharose, respectively. Specific elution of bound protein from the 25.77 antibody column was achieved at pH 8.0 with 2 M potassium thiocyanate and 50 mM diethylamine, pH 11.5, was used for specific elution of protein bound to the 25.1 antibody column. After a second cycle of absorption and elution the purity of the protein preparations was assessed by SDS-PAGE. Essentially, the only polypeptides present were

**Fig. 1** P. y. yoelii polypeptides analysed by SDS-PAGE<sup>7</sup> in 7.5% gels. In tracks a, b and e, f, the polypeptides are labelled with  $^{35}$ S-methionine and S-methionine and visualized by fluorography, and in tracks c, d, they are stained with Coomassie blue. Track a, products immunoprecipitated with antibody 25.1; track b, immunoprecipitation with antibody 25.77; track c, protein purified by monoclonal antibody affinity chromatography using antibody 25.1; track d, protein purified by monoclonal antibody affinity chromatography using antibody 25.77; track e, <sup>35</sup>S-labelled polypeptides immunoprecipitated by serum from mice immunized with the protein preparation shown in track c track f, products immunoprecipitated by serum from mice immunized with the protein preparation shown in track d. A schizont-enriched fraction of parasitized erythrocytes, prepared by centrifugation through a layer of Histopaque (Sigma)<sup>8</sup>, was labelled with <sup>35</sup>S-methionine as previously described<sup>2</sup>. Labelled (for immunoprecipitation) or unlabelled (for affinity chromatography) parasitized erythrocytes were extracted on ice in at least 5 chromatography) parasitized erythrocytes were extracted on ice in at least 5 volumes of a buffer containing 50 mM Tris-HCl pH 8.0, 5 mM EDTA, 5 mM EGTA, 5 mM iodoacetamide, 1 mM phenylmethyl sulphonyl fluoride, 0.1 mM TLCK, and 1% (v/v) NP40. Insoluble material was removed by centrifuging at 100,000g for 45 min at 4 °C. Formalin-fixed Cowan I strain Staphylococcus aureus organisms were used to precipitate immune complexes? For fluorographic visualization, gels were treated with En<sup>3</sup>Hance (NEN) before exposure at -70 °C using Kodak X-Omat H film. Monoclonal antibodies were purified from ascitic fluid from BALB/c mice carrying hybridoma lines WIC 25.1 and WIC 25.77 using Protein A-manufacturer's recommended method, and equilibrated with 10 mM Tris-HCI pH 8.0, 1 mM EDTA, 1 mM EGTA, 1% (v/v) NP40, at 4 °C. The 25.77 antibody-Sepharose column was washed with equilibration buffer containing 0.5 M NaCl then with 10 mM Tris-HCl pH 8.0, 1 mM EDTA,  $1~\rm mM~EGTA,\,0.01\%~NP40,$  and then bound protein was eluted using 2 M KSCN in the same buffer. The eluate was dialysed against 0.1%~NP40 and reapplied to the column. Retained material was re-eluted using 2 M KSCN,

0.01% NP40, concentrated and dialysed. The 25.1 antibody-Sepharose column was washed with equilibration buffer containing 0.5 M NaCl, then with buffer containing 0.1% NP40. Bound material was eluted with 50 mM diethylamine pH 11.5, 0.1% NP40. The eluate was dialysed against the pH 8.0 buffer containing 0.1% NP40, and applied a second time to the re-equilibrated column. The column was washed with 10 mM Tris-HCl pH 8.2, 1 mM EDTA, 1 mM EGTA, 0.5% (w/v) sodium deoxycholate, and the retained material was eluted with 50 mM diethylamine pH 11.5, 0.5% sodium deoxycholate, concentrated and dialysed. 400 µg of protein was routinely recovered from the 25.77 antibody-Sepharose column, and the 25.1 antibody-Sepharose column yielded some 1,600 µg of protein. Antisera against the purified P. y. yoelii proteins for immunoprecipitation analysis (tracks e, f) were raised in BALB/c mice as described in the Fig. 4 legend. Molecular weight markers were human spectrin heterodimer (240,000 and 220,000), phosphorylase b (93,000), bovine serum albumin (68,000) and aldolase (39,000).

identical to those previously detected in the monoclonal antibody immunoprecipitates (Fig. 1c, d).

The relationship between the polypeptides recognized by antibody 25.1 was revealed by pulse-chase labelling of *P. y. yoelii* schizonts with <sup>35</sup>S-methionine *in vitro*, followed by solubilization and immunoprecipitation of samples at various time intervals after labelling. The label was initially

incorporated into the 230,000 MW polypeptide, then during further incubation it sequentially appeared in the smaller polypeptides, with a concomitant reduction in the amount of label remaining in the 230,000 MW component (Fig. 2). Thus, the native antigen recognized by antibody 25.1 is a 230,000 MW protein and the smaller polypeptides are proteolytic fragments of it, each retaining the antigenic determinant recognized by the

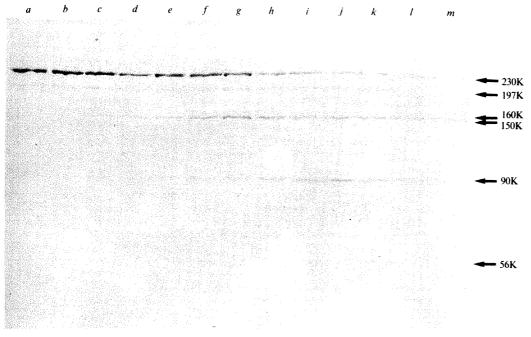

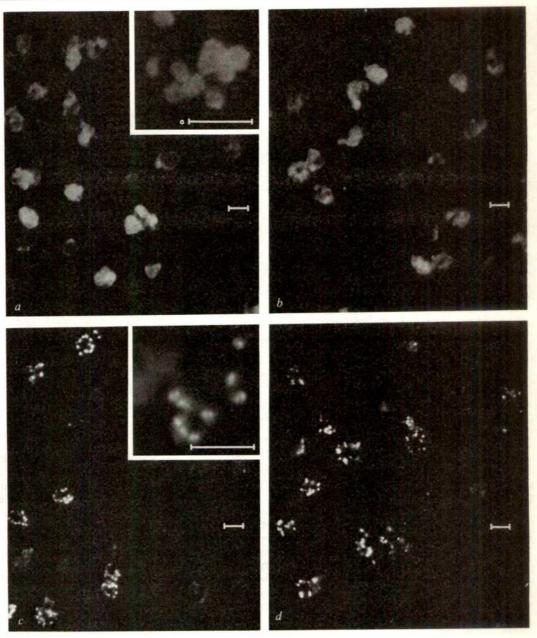

Fig. 2 Processing of the 230,000 MW schizont protein during incubation P. y. yoelii-parasitized erythrocytes in vitro. Parasitized erythrocytes  $(4 \times 10^9)$  were incubated at 37 °C in 8.0 ml of methionine-free RPMI 1640 (Gibco) tissue medium supplemented with 10 µCi ml<sup>-1</sup> 35S-methionine (Amersham). After 10 min, 400 µl of 50 mM methionine was added, and 0.5-ml aliquots of cell suspension were removed at the times indicated. The cells were washed with ice-cold RPMI 1640 and then frozen at -80 °C. The frozen cell pellets were thawed by addition of 0.5 ml of 50 mM Tris-HCl pH 8.0, 5 mM EDTA, 5 mM EGTA, 5 mM iodoacetamide, 1 mM phenylmethyl sulphonyl fluoride, 0.1 mM TLCK, 1% (v/v) NP40, and used for immunoprecipitation using antibody 25.1. After SDS-PAGE on

a 7.5% gel, 35S-labelled polypeptides were detected by fluorography at -70 °C. The estimated MWs of the immunoprecipitated polypeptides are indicated (see Fig. 1). Duration of chase (min); a, 0; b, 10; c, 20; d, 40; e, 60; f, 90; g, 120; h, 150; i, 180; j, 240; k, 300; l, 360; m, 420.

Fig. 3 IIF staining reactions on acetone-fixed P. y. yoelii YM antigen smears, using serum from BALB/c mice carrying the hybridoma lines WIC 25.1 (a) and 25.77 (c), or using serum from mice immunized with the 230,000 MW P. y. yoelii protein and its fragments (b) and the 235,000 MW P. y. yoelii protein (d), as described in Fig. 4 legend. The IIF assay was performed as previously described<sup>1</sup>, using immuno-absorbent-purified fluorescisothiocyanate-labelled rabbit anti-mouse IgG. Inset a, IIF reaction of antibody 25.1 on a mature segmented schizont. Note localization of staining to a membrane surrounding individual merozoites. Inset c, IIF reaction of antibody 25.77 on a mature segmented schizont. Note localization of staining to a small area on each merozoite. Scale bar, 5 µm.

monoclonal antibody. Amino acid sequence homology between the major immunoprecipitated polypeptides was confirmed by two-dimensional chymotryptic peptide mapping (data not shown). In vitro, degradation or processing of the native protein began soon after its synthesis and was extensive after 7 h (Fig. 2). The results indicate that the processing occurred during incubation of the intact schizonts rather than after cell lysis and solubilization. As a consequence of the phenomenon, our purified 25.1 protein preparations always contained fragments of the 230,000 MW protein as well as the intact protein.

In the IIF test, antibody 25.1 reacted with free merozoites in suspension, indicating that the 230,000 MW protein (or fragments of it) is located on the merozoite surface. Using acetone-fixed schizonts, the IIF staining by antibody 25.1 suggests that the 230,000 MW protein is synthesized before merozoite formation and is associated specifically with the plasma membrane of the developing intracellular parasite (Fig. 3a), rather than with the host erythrocyte plasma membrane as suggested previously<sup>2</sup>. In early schizonts the antigen seems to be localized at a spherical membrane enclosing the parasite, but following segmentation and formation of the residual body, the staining is evenly distributed over each merozoite (Fig. 3a, insert).

Antibody 25.77 did not react with free merozoites in suspension in the IIF test, and with acetone-fixed schizonts the reaction was localized to a region within each merozoite (Fig. 3c, insert). It seems, therefore, that the 235,000 MW protein is not on the surface, but may be associated with intracellular organelles of the mature merozoite.

Groups of BALB/c mice were immunized with the two P. y. yoelii protein preparations on three occasions. One week after the third immunization, the mean serum titres were 1 in 10,240 (merozoite-specific) for the group immunized with the 235,000 MW protein, 1 in 10,240 (schizont-specific) for the group immunized with the 230,000 MW protein and its fragments, and 1 in 40 (nonspecific) for the control group.

The sera from the immunized mice immunoprecipitated the same polypeptides as did the monoclonal antibodies (Fig. 1e, f), and produced IIF staining patterns indistinguishable from those produced by the monoclonal antibodies (Fig. 3), confirming the immunogenicity and purity of the parasite protein preparations.

The groups of mice immunized as described were challenged by intravenous (i.v) injection of 10,000 P. y. yoelii YM-parasitised erythrocytes. In the control group, parasitaemia increased rapidly and all mice in this group died on day 8 after challenge (Fig. 4). In contrast, the mice immunized with the 230,000 MW protein and its fragments showed relatively low-grade parasitaemias which were cleared from blood smears by day 10, and all mice in this group survived. In the group immunized with the 235,000 MW protein, parasitaemia was initially suppressed

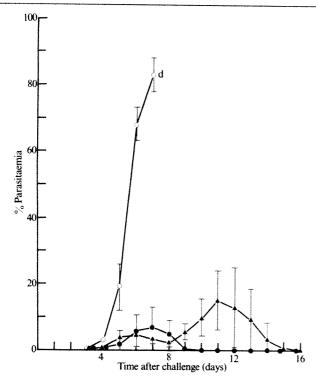

Fig. 4 Mean parasitaemias in groups of five BALB/c mice challenged with 10,000 P. y. yoelii YM-parasitized erythrocytes, after immunization with the P. y. yoelii protein and its fragments (1), or with the 235,000 MW P. y. yoelii protein (\( \begin{array}{c} \) or saline (\( \cappa \)). The P. y. yoelii proteins were purified as described in Fig. 1 legend, and the immunization protocol was as follows: 12 µg of protein in Freund's complete adjuvant (FCA) given intraperitoneally (i.p.) on days 0 and 35, and 20 µg of protein in saline given i.v. on day 50. In the control group, 0.1 ml of saline in FCA was given i.p. on days 0 and 35, and 0.1 ml of saline was given i.v. on day 50. The challenge infection was given i.v. on day 60. Parasitaemia was scored daily by microscopic counting of parasitized erythrocytes in smears of tail blood stained with Giemsa's stain. Mean survival time in the control group is indicated (d). The vertical bars indicate standard deviations

relative to controls, but after day 8 an influx of reticulocytes into the circulation was coincident with an increase in parasitaemia, with all parasites confined to reticulocytes. However, parasitaemias in this group were cleared from blood smears by day 16, and all the mice immunized with the 235,000 MW protein survived.

Immunization with the 230,000 MW schizont antigen and its fragments induced an immune response equally effective against parasites in reticulocytes and in mature erythrocytes. In immunized mice, challenge infection developed normally for the first 3 days, was then suppressed relative to controls, and cleared over the following 7 days. This observation indicates that resistance to infection in these mice was not due simply to the serum antibody response to immunization. The kinetics of challenge infection were similar to those in mice immunized with whole formalin-fixed, free P. y. yoelii parasites described by Playfair et al.3. These workers have implicated both humoral and cellmediated immune responses in the mechanism of parasite clearance in mice immunized with whole parasites<sup>4,5</sup> and it will be important to analyse further the mechanisms mediating immunity in mice immunized with the purified P. y. yoelii proteins.

The ability of P. y. yoelii strains to invade mature erythrocytes is an important factor in their virulence<sup>6</sup>. As had previously been observed<sup>2</sup> after passive transfer of antibodies 25.77 and 25.37. challenge infections in mice immunized with the 235,000 MW merozoite antigen were confined to reticulocytes, and the infections were non-lethal. In unimmunized controls, on the other hand, mature erythrocytes also became extensively parasitized, leading to the deaths of these mice. How the 235,000 MW antigen might be involved in host cell specificity and virulence of P. y. yoelii is not understood.

Other protective P. y. yoelii antigens may exist, and it should be possible, using the approach described here, to identify and characterize them. To extend the present findings, it will be important to determine whether proteins analogous to the 230,000 MW and 235,000 MW antigens of P. y. yoelii are synthesized by other malaria parasites, in particular the human malaria parasite, Plasmodium falciparum.

We thank Lynn Bushby, Lynne Davey and Sheila Graves for technical assistance and Dr G. A. M. Cross for helpful discussions.

#### Complete in vitro maturation of Plasmodium falciparum gametocytes

#### T. Ifediba & J. P. Vanderberg

Division of Parasitology, Department of Microbiology, New York University Medical School, New York, New York 10016, USA

The form of malaria caused by Plasmodium falciparum is probably the most important infectious disease of man. In tropical Africa alone, where malaria affects almost the entire population, it has been estimated that every year the disease causes the death of 1 million children under 14 yr old1. The mosquito vector of malaria is infected when it ingests mature gametocytes in blood taken from a human carrier of the disease. Development of the parasite continues in the mosquito and culminates with the sporozoite stage, which initiates a new infection when injected by the mosquito into a further human host. Research on P. falciparum sporozoites has been severely limited by a general lack of availability of suitable patients with gametocytes. It was hoped that the recently developed continuous cultivation of *P. falciparum*<sup>2</sup> would solve this, as gametocytes are often produced during cultivation. However, we and others soon found that these gametocytes failed to mature in culture<sup>3,4</sup>, or at best did so only rarely and unpredictably<sup>5-7</sup>. We report here that addition of hypoxanthine to the culture medium permits the production of mature, infectious P. falciparum gametocytes on a regular basis.

Gametocyte production involves two distinct processes: an inductive process that commits certain asexual parasites to become gametocytes, and a developmental process that supports the full differentiation of these committed cells<sup>3</sup>. Gametocyte induction has been shown to occur more readily when the cultures are maintained for extended periods of time without the addition of fresh uninfected erythrocytes<sup>4,6</sup>. We have found that this induction process is enhanced when the erythrocyte concentration is reduced for part of the culture period, and when old cultures with mature gametocytes are used to initiate new cultures (Table 1). When the erythrocyte concentration was reduced to 6%, the resulting gametocytaemia was almost double that observed for an erythrocyte concentration of 12%. Interestingly, the absolute numbers of gametocytes per culture flask remained about the same in both cases.

Gametocytes grown in these conditions, and with added hypoxanthine (50 μg ml<sup>-1</sup>), developed to functional maturity (as determined by their infectivity for mosquitoes (Tables 2-4)). When the gametocytes were collected 12-14 days after initiation of the cultures, mosquitoes in each of 18 groups that fed on

Table 1 Effect of erythrocyte concentration on production in vitro of Plasmodium falciparum gametocytes

Strain	Erythrocyte concentration	No. of cultures	Gametocytaemia*
Honduras	12%	72	$1.5 \pm 0.5\%$
110	6%	74	$2.7 \pm 0.5\%$
Z	12%	23	$1.4 \pm 0.6\%$
	6%	24	$2.9 \pm 0.6\%$
FCN-2	12%	28	$1.0 \pm 0.5\%$
	6%	26	$2.3 \pm 0.6\%$

All cultures were initiated at 0.2% parasitaemia and 12% haematocrit in RPMI-1640 with HEPES<sup>2</sup>, 15% (v/v) human serum and 50 µg ml<sup>-1</sup> hypoxanthine (Sigma). Human erythrocytes were used within a few days after collection. Cultures were grown at 37 °C in tissue culture flasks (75 cm<sup>2</sup>) in a total volume of 20 ml per flask, in an atmosphere of 3% O<sub>2</sub>, 2% CO<sub>2</sub> and 95% N (ref. 15). Medium was changed daily by removal of spent medium and addition of fresh medium prewarmed to 37 °C. No new erythrocytes were added during the culture period. At 7 days the haematocrit of some cultures was reduced to 6%, and daily feeding of all cultures continued with the same medium, but with the human serum component reduced to 10%. Gametocytaemia was determined at 12-14 days, and these mature cultures were used to initiate new gametocyte cultures. The Honduras strain was from CDC, Z was obtained from NIH and FCN-2 was isolated from blood of a patient from Bangkok.

\* Number of gametocytes (±s.d.) per 100 erythrocytes, determined from Giemsa-stained smears.

them developed midgut infections consisting of substantial numbers of oocysts. In each of these groups, the percentage of mosquitoes that went on to develop salivary gland infections of sporozoites was comparable to the percentage with oocyst infections. Sporozoites collected from the salivary glands appeared normal, and had motility typical of *P. falciparum* sporozoites<sup>8</sup>.

Complete gametocyte maturation did not normally occur in parallel control cultures without added hypoxanthine (Table 2). Gametocytes in these control cultures appeared morphologically normal, but were generally not infective for mosquitoes. In a single case, a mosquito fed on gametocytes from these control cultures was found to have one oocyst in its midgut.

Asexual, erythrocytic malarial parasites are known to require exogenous sources of purines for their metabolism, but rely on de novo synthesis of pyrimidines<sup>9</sup>. Studies of the sporogenic

Table 2 Effects of hypoxanthine on gametocyte maturation in infected vectors

	No. of mosquitoes infected with oocysts					
Expt	Hypoxanthine (50 µg ml <sup>-1</sup> )	No hypoxanthine				
1	11/17 (65%)	0/15 (0%)				
2	8/20 (40%)	0/20 (0%)				
3	14/18 (78%)	1/17* (6%)				
4	13/20 (65%)	0/13 (0%)				
5	10/16 (63%)	0/15 (0%)				

Gametocytes (Honduras strain) were cultured as described in Table 1 legend, with or without hypoxanthine added to the culture medium, and collected 13-14 days after initiation of the cultures. Cells in the culture flask were sedimented, after which 2-3 vol of uninfected human erythrocytes were added together with sufficient human serum to give a 50% haematocrit, and fed to Anopheles stephensi mosquitoes using a membrane feeder 16. Mosquitoes were maintained according to standard procedures 17 and received a blood meal from an uninfected hamster on day 6. Midgut infections were determined 10-14 days after the infective feeding. Values shown are the results of individual experiments.

\* Infection with single oocyst.

Gametocytes were cultured with added hypoxanthine and fed to mosquitoes as described in legends to Tables 1 and 2. Midgut infections were determined 10-14 days after the infective feeding. Values shown are the results of individual experiments.

stages of the parasite suggest that a similar situation may hold for ookinetes<sup>10</sup> and sporozoites<sup>11</sup>. There is evidence<sup>9</sup> that the key exogenous purine incorporated by the parasite is hypoxanthine. We have previously pointed out<sup>3</sup> that RPMI-1640 is a relatively simple tissue culture medium that supplies all nutritional requirements for asexual parasites but that gametocytes may require additional growth factors for full development. For successful cultivation of asexual parasites, the host erythrocyte is obliged to supply nutrients for only the 48-cycle of the parasite's development within it, whereas the developing gametocyte occupies its host erythrocyte for 2 weeks or longer. For complete gametocyte maturation to occur, the depleted hypoxanthine reserves of the host erythrocyte apparently must be supplemented by an exogenous source. Our finding that hypoxanthine may be a limiting factor in the culture of P. falciparum gametocytes should now permit large-scale production of mature gametocytes for further immunization studies using gametes<sup>12</sup> or sporozoites<sup>13,14</sup> of this species.

We thank R. Nawrot and M. Silcott for technical assistance. This study was supported by the US Agency for International Development under contract AID/ta-C-1486.

#### Opposing roles for D-1 and D-2 dopamine receptors in efflux of cyclic AMP from rat neostriatum

#### J. C. Stoof\* & J. W. Kebabian

Experimental Therapeutics Branch, National Institute of Neurological and Communicative Disorders and Stroke, National Institutes of Health, Bethesda, Maryland 20205, USA

Two types of dopamine receptor whose stimulation affects cellular cyclic AMP have now been identified. In tissues as different as insect ganglia and mammalian neostriatum, stimulation of the dopamine receptor called D-1 increases formation of cyclic AMP<sup>1-6</sup>, whereas stimulation of the second type of dopamine receptor (D-2)<sup>7-11</sup>, first identified in the rat pituitary gland, reduces cyclic AMP formation. Recently, a receptor with the pharmacological properties of the D-2 receptor has also been found 12-14 in the rat neostriatum; we show here that stimulation of this receptor is followed by a reduction in cyclic AMP formation induced by V stimulation with D-1 agonists.

Previous investigations of the dopaminergic regulation of neostriatal cyclic AMP formation have determined either adenylate cyclase activity of tissue homogenates<sup>2</sup> or cyclic AMP content of tissue slices<sup>15</sup>. However, we have used as a biochemical sign of dopamine receptor stimulation the dopaminergic enhancement of cyclic AMP efflux from slices of neostriatum because cyclic AMP efflux is a particularly sensitive indicator of hormone-stimulated cyclic AMP formation in the adrenal cortex<sup>16,17</sup>. Blocks of rat neostriatum were superfused with Earle's balanced salt solution, to which were added isobutyl methylxanthine<sup>18</sup> (1 mM) and bovine serum albumin (BSA; 2.5 mg ml<sup>-1</sup>) in a 16-chamber superfusion apparatus described elsewhere 19. After 60 min of superfusion, several fractions were collected for each chamber, and dopaminergic drugs were added to the medium and additional fractions collected. At the end of the experiment, the cyclic AMP content of each fraction was determined by radioimmunoassay.

SKF 38393 is an agonist equipotent (on a molar basis) to dopamine on the D-1 dopamine receptor 4,20,21, but substantially less potent (on a molar basis) when tested on the pituitary D-2 dopamine receptor 11,20. SKF 38393 caused a time- and dosedependent increase in the efflux of cyclic AMP from blocks of rat neostriatum (Fig. 1a, b), the maximal effect being a 3.5-fold enhancement of cyclic AMP efflux which occurred after 25 min. This maximal effect on cyclic AMP efflux was greater than the maximal effect of the agonist on either the cyclic AMP content of neostriatal blocks (1.6-fold enhancement; see Fig. 1 legend) or

Table 1 Fluphenazine inhibits SKF 38393-stimulated efflux of cyclic

Drug	Cyclic AMP efflux (% of basal efflux)
None	$99.8 \pm 12.7$
SKF 38393 (1 μM)	$304.0 \pm 18.5$
SKF 38393 $(1 \mu M)$ + fluphenazine $(1 \mu M)^*$	$194.3 \pm 12.3 \dagger$
SKF 38393 $(1 \mu M)$ + fluphenazine $(10 \mu M)^*$	$121.8 \pm 2.4 \dagger$

Experimental procedures were as described for Fig. 1a, Basal efflux of cyclic AMP was determined for three successive 10-min fractions collected between 60 and 90 min. Exposure to drugs began at 90 min. Cyclic AMP efflux in the final fraction (115-125 min) was expressed as mean % of basal efflux (±s.e.m.) of observations made on four superfusion chambers (as described for Fig. 1b).

Fluphenazine was added 30 min before SKF 38393 (see ref. 29).

on the adenylate cyclase activity (1.7-fold enhancement<sup>20</sup>). SKF 38393 half-maximally enhanced cyclic AMP efflux at a concentration of  $2 \times 10^{-7}$  M (Fig. 1c), which is about the same as the concentration (10<sup>-7</sup> M) reported half-maximally to activate neostriatal adenylate cyclase activity<sup>20</sup>. Fluphenazine markedly attenuated the SKF 38393-stimulated efflux of cyclic AMP (Table 1). However (-)sulpiride, an antagonist on the pituitary D-2 dopamine receptor<sup>11,22</sup> which has no antagonist action on the D-1 receptor<sup>23</sup>, did not alter the basal efflux of cyclic AMP and induced a statistically insignificant potentiation of the SKF 38393-stimulated efflux (Fig. 2a). These results demonstrate that the efflux of cyclic AMP from blocks of rat neostriatum provides a biochemical sign of stimulation of the D-1 receptor in this tissue.

LY-141865, an agonist on the pituitary D-2 receptor<sup>24,25</sup> which has no effect on the D-1 receptor in fish retina25 or rat neostriatum (E. Frey, unpublished results), did not stimulate the efflux of cyclic AMP either in the presence or absence of (-)sulpiride (Fig. 2b). Dopamine, an agonist on both the D-1 (refs 1-6) and D-2 (refs 11, 26, 27) dopamine receptors, increased the efflux of cyclic AMP from blocks of rat neostriatum (Fig. 2c). Interestingly, (-)sulpiride markedly potentiated the dopamine-stimulated efflux of cyclic AMP whereas (+)sulpiride was ineffective (Fig. 2c). Furthermore, apomorphine, which also stimulates both dopamine receptors<sup>1-4,11,26,27</sup>, enhanced the efflux of cyclic AMP only in the presence of (-)sulpiride (Fig. 2d).

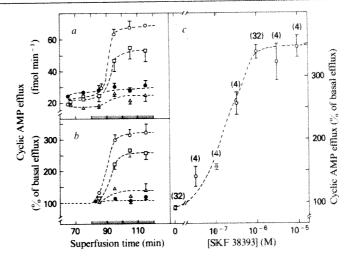

LY-141865 reduced the SKF 38393-stimulated efflux of cyclic AMP, the maximal effect being a reduction of  $57 \pm 8\%$ (data from four separate experiments; Fig. 3). This inhibitory effect was reversed by ( – )sulpiride (Fig. 3). LY-141865 did not significantly inhibit the (-)isoprenaline-stimulated efflux of cyclic AMP: cyclic AMP efflux induced by (-)isoprenaline  $(1 \mu M)$  was  $514.3 \pm 33.8$  (% of basal efflux) compared with  $452.0 \pm 28.3\%$ for (-)isoprenaline  $(1 \mu M) + LY-141865$  $(1 \mu M)$ .

Based on the results obtained with dopamine, apomorphine and LY-141865, we propose the existence in the neostriatum of a second dopamine receptor, regulating the efflux (and by inference the formation) of cyclic AMP. Stimulation of this second receptor inhibits the formation of cyclic AMP occurring as a consequence of stimulating the D-1 dopamine receptor. According to this interpretation, dopamine interacts with both types of receptor in the neostriatum, simultaneously stimulating and inhibiting the formation and efflux of cyclic AMP. (-)Sulpiride potentiates the dopamine-stimulated efflux by blocking the second dopamine receptor, removing the inhibitory constraint on the formation of cyclic AMP and thereby stimulating the observed efflux of cyclic AMP. Similarly, apomorphine stimulates both dopamine receptors; (-)sulpiride antagonizes the interaction between apomorphine and the second dopamine receptor, thereby permitting the interaction between apomorphine and the D-1 receptor to be expressed as

Fig. 1 SKF 38393 stimulates efflux of cyclic AMP from blocks of rat neostriatum. a, Time course of cyclic AMP efflux. Tissue was superfused without drug ( $\bullet$ ) or with SKF 38393 ( $\triangle$ ,  $3 \times 10^{-8}$  M;  $\square$ ,  $3 \times 10^{-7}$  M;  $\bigcirc$ ,  $3 \times 10^{-8}$  M). Exposure to SKF 38393 (thickened abscissa) began at 80 min. Data represent mean  $\pm$  s.e.m. (n = 4) of the cyclic AMP content of superfusion medium collected during the indicated time periods. At the end of the experiment, tissue content of cyclic AMP was 312 ± 14 fmol per mg wet weight in the absence of SKF 38393 and  $352\pm6$ ,  $428\pm22$  and  $506\pm32$  fmol per mg wet weight in the presence of  $3\times10^{-8}\,\mathrm{M}$ ,  $3\times10^{-7}\,\mathrm{M}$  and  $3\times10^{-6}\,\mathrm{M}$  SKF 38393 respectively. In all experiments, brains of eight male Sprague–Dawley rats  $(250-300\,\mathrm{g})$  were removed and placed in a special holder. Two successive 2 mm-thick coronal brain slices were made between the anterior planes A 7,000 and A11,000 µm (ref. 30). Neostriatal tissue was dissected from these two slices and cut twice with a McIlwain tissue chopper (300 μ); before the second pass, the chopping surface was rotated 90°. The resulting blocks of neostriatal tissue (2 × 0.3 × 0.3 mm) were transferred to Earle's balanced salt solution (EBSS) and stored until neostriatal tissue had been obtained from all rats. Aliquots

(20 mg wet weight) of the chopped neostriatal tissue were placed in each of 16 chambers of a superfusion apparatus<sup>19</sup> and superfused at a rate of 0.1 ml min<sup>-1</sup> with EBSS (37 °C) containing BSA (2.5 mg ml<sup>-1</sup>) and 3-isobutyl-1-methylxanthine<sup>18</sup> (1 mM). After 60 min of superfusion, two or three 1.0-ml fractions (as indicated in the legends) were collected from each chamber; drugs were added to the superfusion medium and additional fractions collected from each chamber. Although no antioxidant was included during the superfusion, decomposition (as determined by HPLC with electrochemical detection) of drugs known to be sensitive to oxidation, such as dopamine, (-)isoprenaline or apomorphine, was <10% during the 30 min of superfusion. Each data point on the ordinate represents the midpoint of the collection period (for example, the data obtained from fractions collected between 80 and 90 min are located at a superfusion time of 85 min). At the end of the experiment, the tissue was superfused for 20 min with 0.1 M HCl to extract cyclic AMP from the tissue. The cyclic AMP content of duplicate 100-µl aliquots of each fraction was estimated by radioimmunoassay (RIA) as described elsewhere<sup>31</sup> using RIA kits (NEN); the limit of detection of this RIA was 2.5 fmol per 100 µl. b, Data from a transformed mathematically. The ability of SKF 38393 to enhance cyclic AMP efflux was calculated from data in a (the same symbols are used). Every chamber served as its own control; for each chamber, the basal efflux of cyclic AMP (that is, the mean amount of cyclic AMP in the fractions collected before drug addition) was calculated, and the amount of cyclic AMP determined from data obtained in nine separate experiments; the SKF 38393-induced stimulation of cyclic AMP efflux was calculated as in b. The data represent SKF 38393-stimulated cyclic AMP efflux in the last collected fraction (for example, the fraction collected between 110 and 120 min in a). Values represent mean ± s.e.m.; n, indicated in parentheses, is the number of supe

Fig. 2 Effects of dopaminergic agonists and sulpiride on efflux of cyclic AMP from blocks of rat neostriatum. Experimental procedures were as described for Fig. 1a. Basal efflux of cyclic AMP was determined from three successive 10-min fractions collected between 60 and 90 min. Exposure to drugs (thickened abscissa) began at 90 min. Cyclic AMP efflux was expressed as the mean % basal efflux (±s.e.m.) of observations made on four superfusion chambers (as described for Fig. 1b). a, Tissue was superfused without drug (●), or with 10<sup>-6</sup> M (−) sulpiride (□), 10<sup>-6</sup> M SKF 38393 (○) or 10<sup>-6</sup> M (−) sulpiride and 10<sup>-6</sup> M SKF 38393 (△). b, Tissue was superfused without drug (●) or with 10<sup>-6</sup> M LY-141865 (○) or 10<sup>-6</sup> M LY-141865 and 10<sup>-6</sup> M (−) sulpiride (△). (LY-141865 is designated 'compound 38, R = pro' in ref. 24.) c, Tissue was superfused without drug (●) or with 8×10<sup>-6</sup> M dopamine (○), 8×10<sup>-6</sup> M dopamine and 2×10<sup>-6</sup> M (−) sulpiride (△), or 8×10<sup>-6</sup> M dopamine and 2×10<sup>-6</sup> M (+) sulpiride (▲). d, Tissue was superfused with 5×10<sup>-7</sup> M apomorphine alone (○) or in combination with 10<sup>-6</sup> M (−) sulpiride (△).

an enhanced efflux of cyclic AMP (although apomorphine can also antagonize the D-1 receptor  $^{3,21}$ , our experiments were not designed to demonstrate this property). The SKF 38393-stimulated efflux of cyclic AMP was not significantly potentiated by (—)sulpiride because, at a concentration of 1  $\mu$ M, SKF 38393 stimulates the D-1 dopamine receptor without having a significant effect on the D-2 receptor. However, the SKF 38393-

stimulated efflux of cyclic AMP was diminished by LY-141865 as a consequence of the interaction between LY-141865 and the second, pituitary-like D-2 dopamine receptor. Accordingly, this effect of LY-141865 was blocked by (-)sulpiride.

In the intermediate lobe of the rat pituitary gland, a  $\beta$ -adrenoceptor and a D-2 dopamine receptor occur on the same cell. Stimulation of the D-2 dopamine receptor decreases the

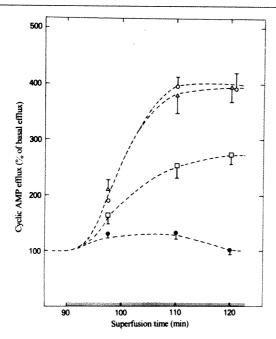

Fig. 3 Inhibitory effect of LY-141865 on SKF 38393-stimulated efflux of cyclic AMP is antagonized by (-)sulpiride. Experimental procedures were as described for Fig. 1a. Basal efflux of cyclic AMP was determined from three successive 10-min fractions collected between 60 and 90 min. Exposure to drugs (thickened abscissa) began at 90 min. Efflux of cyclic AMP was expressed as the mean % basal efflux (±s.e.m.) of observations made on four superfusion chambers (as described for Fig. 1b). Tissue was superfused without drug (●), or with 10<sup>-6</sup> M SKF 38393 (○), 10<sup>-6</sup> M SKF 38393 and 10<sup>-6</sup> M LY-141865 (□), or with 10<sup>-6</sup> M SKF 38393, 10<sup>-6</sup> M LY-141865 and 10<sup>-6</sup> M (−)sulpiride (△).

formation of cyclic AMP stimulated by  $\beta$ -adrenergic agonists. By analogy with the situation in the intermediate lobe, the biphasic regulation of cyclic AMP formation by dopamine raises the possibility that both the D-1 and D-2 dopamine receptors are associated with the same cell in the neostriatum. However, it is possible that stimulation of the D-2 receptor decreases the responsiveness of the D-1 receptor by an indirect, trans-synaptic process. Although a  $\beta$ -adrenoceptor enhances cyclic AMP formation in the neostriatum<sup>15,28</sup>, the failure of LY-141865 to affect significantly the (-)isoprenaline-stimulated efflux of cyclic AMP suggests that the D-2 dopamine receptor and the  $\beta$ -adrenoceptor are not functionally connected in the neostriatum. Although our data demonstrate a biochemical consequence of stimulation of the D-2 dopamine receptor in the neostriatum, the ultimate physiological consequences of stimulation of either the D-1 or the D-2 receptor in this area of the brain remain unknown.

#### Single channel potassium currents of the anomalous rectifier

#### Yasuo Fukushima

Laboratory of Neurobiology, Institute of Brain Research, School of Medicine, University of Tokyo, Hongo 7-3-1, Bunkyo-ku, Tokyo, Japan

The recording of single channel currents has revealed the discrete events underlying the conductance changes for the Na and delayed K currents of the action potential, as well as those underlying acetylcholine-evoked currents<sup>1-5</sup>. The existence of similar discrete events has been suggested by noise analysis of the current termed anomalous K rectifier<sup>6,7</sup>, in which a K conductance is increased by hyperpolarization or by an increased extracellular concentration of K ions8. I have now used the patch current recording technique to investigate the anomalous rectifier of the tunicate egg cell. The statistics of pulse-like events in the patch current were found to be consistent with the inactivation kinetics of the anomalous rectifier. The extrapolated zero-current potential of the pulse-like events was approximately equal to that of the total anomalous K current. The single channel conductance was 5.2 pS in 50 mM K solution.

Tunicate egg cells were voltage-clamped with two microelectrodes as described previously9. The bath saline contained 200 mM NaCl, 360 mM choline chloride and 10 mM MnCl<sub>2</sub>, pH 7.0, and was maintained at 13.5-15.5 °C. A clean membrane surface was obtained by enzymatic digestion of the chorion. Patch current was recorded with a current-voltage converter which had a feedback resistor of 500 M $\Omega$ . The patch electrode was a conventional micropipette that had not been fire polished, and was filled with saline similar to that in the bath, except that 50, 100 or 200 mM K replaced an equal amount of choline. CaCl<sub>2</sub> (10 mM) and MgCl<sub>2</sub> (30 mM) were used as divalent salts; later 10 mM MnCl<sub>2</sub> was found to provide more stable recordings. The resistance of the patch pipette was  $10-50 \text{ M}\Omega$ . When pushed against the egg surface, the seal resistance increased to >1 G $\Omega$  (usually 5-8 G $\Omega$ ). The background noise level was 0.4-0.8 pA (peak-to-peak value, low-pass filtered at 660 Hz with a three-pole Butterworth filter). The rise time between 10 and 90% of the current step recorded by the patch electrode was 0.7-1.0 ms. Current records were digitized at 200 µs per point and stored by an 8-bit, 1K-word transient recorder (Kawasaki Electronica TM 1510).

After obtaining a large seal resistance, 150-ms hyperpolarizing pulses of up to -200 mV were applied to the whole egg cell, from a holding potential of -10 mV. Pulse-like changes in the patch current were observed which had a uniform amplitude at a given membrane potential (Fig. 1c). The pulse-like events in a patch usually disappeared within 20 command pulses. In some such cases, the amplitude of the pulse-like events was reduced in size during the last two or three command pulses and the traces for these were discarded. The current traces at -170 mV in

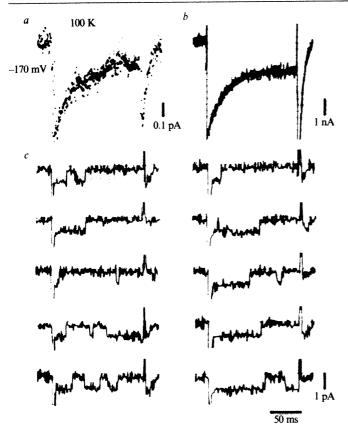

Fig. 1 a, Averaged time course of the pulse-like events in a patch. The whole egg cell was hyperpolarized to  $-170\,\mathrm{mV}$  during 45 command pulses. K concentration in the patch pipette was 100 mM, indicated as 100 K in this and other figures. b, Total membrane K current of the same egg cell in the same solution as in the patch pipette. The estimated number of channels was 7,200 per egg. c, Ten representative traces from the averaged 45 current traces. The inward current after the command pulse in a, b and c was Na current, which was evoked at the holding level of  $-10\,\mathrm{mV}$  after the hyperpolarizing command pulses relieved the inactivation of Na current.

100 mM K solution mostly started with inward deflections after the 3-6-ms capacitative transient and showed two to three pulse-like changes in the patch current during the command pulse lasting 150 ms. Multiples of the unitary amplitude were observed only exceptionally (Fig. 2b), indicating that, in most cases, a single channel existed under the patch pipette. Only the current traces from patches with one channel were analysed. Before or after patch recording the solution in the experimental bath was replaced by that contained in the patch pipette and a conventional voltage-clamp experiment was performed to examine the total anomalous K current. With a hyperpolarizing pulse of -170 mV the total anomalous K current showed an almost instantaneous rise and a subsequent slow exponential decay due to inactivation (Fig. 1b). When the pulse-like events in the patch current obtained at the same potential level were averaged, the time course was similar to that of the total anomalous K current (Fig. 1a). When the command pulse potential was less negative than -170 mV, the amplitude of the pulse-like events became smaller and the number of the events in a current trace decreased. Few or no events were observed at potentials more positive than -130 mV (Fig. 2a, -130 mV).

To analyse the kinetics of the pulse-like events in the patch current, the duration of the first open events was measured and it was denoted as the open time. The closed time was defined as the duration of the lower conductance period following the first open event (Fig. 3); unless it was terminated by another opening, the closed period was not counted. The distribution of the open or closed time showed a monotonic decay with duration; the distribution of the open time at -170 mV was roughly

exponential. The mean open time at  $-130\,\mathrm{mV}$  was markedly longer than at  $-170\,\mathrm{mV}$ , while the mean closed time at  $-130\,\mathrm{mV}$  was slightly shorter than at  $-170\,\mathrm{mV}$ . Assuming that the inactivation process can be described as a first-order transition between the open and closed states,

open state 
$$\stackrel{\alpha}{\underset{\beta}{\longleftarrow}}$$
 closed state

and that all channels are open immediately after the start of the command pulse, the probability density functions for the open time,  $f_{\rm open}(t)$ , and the closed time,  $f_{\rm closed}(t)$ , are

$$f_{\text{open}}(t) = \beta \exp(-\beta t)$$
  
$$f_{\text{closed}}(t) = \alpha \exp(-\alpha t)[1 - \exp\{-\beta (T - t)\}]$$

T is the duration of the command pulse, here equal to 150 ms. The expressions are derived as follows. The probability that a channel remains open at a time t following its opening is  $p = \exp(-\beta t)$ , so the probability density function describing the probability that it closes exactly at t—that its lifetime is t—is

$$f_{\text{open}}(t) = -dp/dt = \beta \exp(-\beta t)$$

A similar expression would describe the probability density function for the closed times, except that the termination of the observation period T by the end of the command pulse reduces the probability of observing long closed times. The reduction depends on the distribution of the open times:

$$f_{\text{closed}}(t) = \alpha \exp(-\alpha t) \int_0^{T-t} \beta \exp(-\beta t') dt'$$
$$= \alpha \exp(-\alpha t) [1 - \exp\{-\beta (T-t)\}]$$

The closing rate constants  $\beta$ , which were estimated from the total anomalous K currents, were 4.01 and  $18.97~{\rm s}^{-1}$ , and the opening rate constants  $\alpha$  12.78 and  $9.46~{\rm s}^{-1}$ , at -130 and  $-170~{\rm mV}$  respectively. In Fig. 3, the probability density functions for single channels estimated from these rate constants are superimposed on the actual distribution by solid thick lines. The actual distributions were in good agreement with the estimated curves; deviations may be due to the small sample

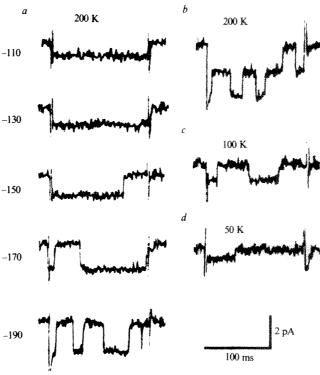

Fig. 2 a, Patch current in 200 mM K solution (200 K). The potential levels (in mV) during the command pulses are shown on the left. b, Current through a patch with two channels in 200 mM K solution. c, d, Patch current in 100 and 50 mM K solutions. The potential levels were  $-170 \,\mathrm{mW}$  in b, c and d.

numbers. The asymmetric dependencies of the opening and closing rate constants on the membrane potential, which were observed from the decay time course of the total anomalous K current, were confirmed in the kinetics of a single channel. It was concluded that the statistics of single channel events in the patch current reflect the inactivation process of the anomalous K rectifier.

The amplitude of the pulse-like events in individual patches was constant at a given membrane potential, with some variations due to the background noise (Fig. 4a). The amplitude of the pulse-like events in a patch was linearly related to the membrane potential in the range -200 to -100 mV (Fig. 4b). Zero-current potentials of the pulse-like events were estimated by extrapolating the least-squares fits to the amplitudes for those patches from which current traces were recorded at least at three membrane potentials. The values of the estimated zero-current

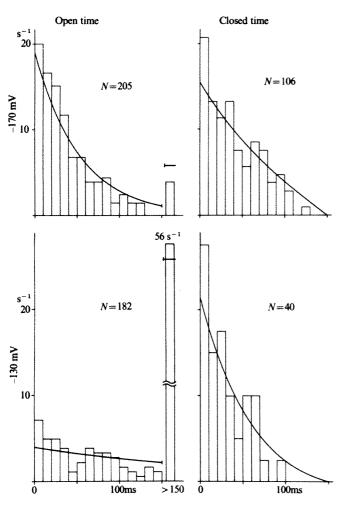

Fig. 3 The distribution of open and closed times, plotted as probability density. The patch current was recorded in 100 mM K solution. Only the first open and closed events of each record were measured, because later events were suspended by the end of the command pulse and accurate measurement of the durations was impossible. Cases in which the channel remained open during the 150-ms command pulse were plotted at the right edge in the distribution of the open times. Cases in which the channel failed to reopen during the command pulse are not included in the distribution of closed times. In the cases where the channel started in the closed state after the artefact, the open event was considered to have terminated during the artefact and was plotted in the first column in the distribution of the open time. The closed time in these cases was calculated by using an open time calculated from the duration of the artefact and the predicted distribution curve. N in each plot is the total sample number, which was normalized to 1 for comparison with the calculated probability density functions. The probability density function for the closed time was normalized by the integral from zero time to 150 ms.

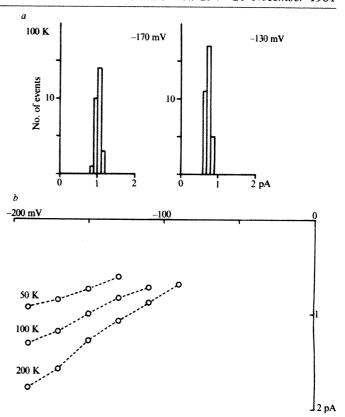

Fig. 4 a, Amplitude distribution of the pulse-like events in a single patch. The membrane potential was -170 and -130 mV in 100 mM K solution. b, Membrane potential and the amplitude of the pulse-like events in a patch. The K concentration in the patch pipette is indicated for each curve. The mean amplitude was plotted for several current traces recorded at a certain potential level.

potentials were  $-35\pm7$ ,  $-30\pm19$  and  $-24\pm14$  mV (mean  $\pm$  s.d.) in 50, 100 and 200 mM K solutions respectively. The zero-current potentials of the total anomalous K current were measured by the resting potentials in Na-free 50, 100 and 200 mM K solutions, giving values of -37, -20 and -3 mV respectively. The difference in the zero-current potentials between those extrapolated from the amplitude of the pulse-like events in the patch current and those measured with the total anomalous K current may be due to a nonlinear current-voltage relationship for single channels.

At -170 mV in 50 mM K solution, the mean amplitude of the pulse-like events occurring in different patches was 0.69 ± 0.14 pA and the single channel conductance was  $5.2 \pm 1.0$  pS, using a zero-current potential of the total anomalous K current. In 100 and 200 mM K solutions, the mean amplitude of the pulse-like events occurring in different patches showed more scattered distribution than that expected from the background noise. Because the statistics of the pulse-like events did not differ between patches, a heterogeneity of channel types is unlikely. Differences in the seal resistance bore no relation to the scattering of the amplitudes. The smaller amplitude of the events may be attributed to the channels under the patch pipette, as proposed in the case of the acetylcholine current<sup>1</sup> The number of channels in an egg was estimated as the ratio of the amplitude of the total anomalous K current in 50 mM K solution at the start of the command pulse to the single channel current of 0.69 pA at -170 mV, where the activation process was almost instantaneously completed and all channels were considered to be initially open. The estimated value was 9,300 ± 6,000 per egg  $(0.041 \ \mu \text{m}^{-2})$ .

Discrete conductance events have been reported in the delayed and Ca-dependent K current<sup>2,10,11</sup>. My experiment shows that single conductance events also underlie the

anomalous K rectifier. The statistics of single channel events are concluded to be derived from the inactivation of the anomalous rectifier because the distribution of the open and closed times coincided with those estimated from the decay time course of the total anomalous K current. The single channel conductances for the anomalous rectifier estimated by the steady-state and ensemble noise analysis were 5.97 and 5.50 pS in 50 mM K . These values are in good agreement with the value of 5.2 pS in 50 mM K solution obtained in the present experiment. Recently the single channel current of the anomalous rectifier has been recorded in rat myotubes and conductance of similar order was obtained12

I thank Professor K. Takahashi for valuable advice at all stages of this work, Dr Y. Yajima for his suggestions in the mathematical analysis, and Professor A. Takeuchi and Dr H. Ohmori for criticism of the manuscript.

#### Gramicidin forms multi-state rectifying channels

#### David Busath & Gabor Szabo

Department of Physiology and Biophysics, University of Texas Medical Branch, Galveston, Texas 77550, USA

Gramicidin A is a pentadecapeptide of alternating L and D amino acids1. In membranes it forms cation conductive channels<sup>2</sup> of molecular dimensions<sup>3,4</sup> that in many respects resemble<sup>2-7</sup> the channels of excitable cells<sup>8,9</sup>. For this reason, and also because its structure is well established 1,10,11, the gramicidin channel is regarded as a useful model of ion channels in cell membranes. Although the properties of the gramicidin channel have been studied extensively<sup>12</sup>, it has generally been described as having a single state associated with a sharply defined conductance that remains unaltered during the lifetime of the channel<sup>13</sup>. We report here that, in fact, gramicidin A can assume other, less conductive 'miniature' (mini) states evidenced by our observations of spontaneous transitions in the conductance of single open channels and the observation of a significant number of weakly conducting channels. Current-voltage (I-V) relationships for different channel states differ significantly and, for minis, are often asymmetrical. Our results indicate that the gramicidin channel has a wide variety of stable conformational states that give rise to channels with different electrical properties. Because transitions between states occur relatively infrequently, these conformational states must be separated by relatively large energies of interconversion. Similar transitions, poised by the electric field or an agonist molecule, may underlie the function of gated channels in cell membranes.

Gramicidin A was purified by HPLC from commercially available gramicidin D (a mixture 14 of gramicidins A, B and C). Membrane currents in the presence of small amounts of gramicidin A were amplified and sampled digitally for computerassisted analysis. For channel conductance measurement (Fig. 1), the electrical potential across the membrane was fixed so that the ionic current through single channels could be monitored directly. For single-channel I-V measurements (Fig. 2), the

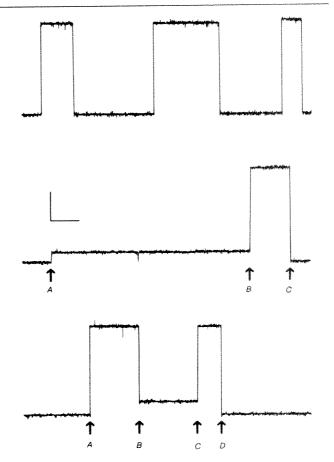

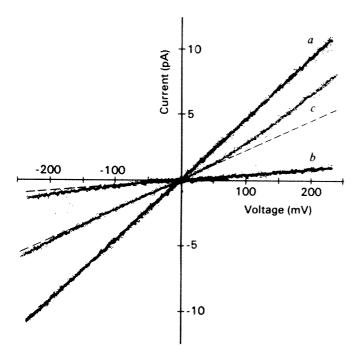

Fig. 1 Time course of the ionic current through single gramicidin A channels. HPLC-purified gramicidin A was added to a bilayer formed from a dispersion of 1-monoolein (50 mg, Nu-Check) in squalene (1 ml, Sigma, purified through silica) and held at 0.1 V. Vertical calibration bar, 1.5 pA. Horizontal bar, 35 s (upper), 10 s (middle) and 15 s (lower). The signal was bandlimited to 30 Hz and sampled 30 times per s. 1M KCL, pH  $\sim$ 5.6, 23  $\pm$  1 °C.

membrane potential was varied at a constant rate, Direct recording of single-channel I-V curves was made possible by reducing the membrane area  $(1.5 \times 10^{-5} \text{ cm}^2)$  so that capacitative current would not obscure the single-channel current.

Channels formed by purified gramicidin A turn on abruptly, that is, with a time course (<200 µs) that cannot be experimentally resolved. The channels typically remain conductive in a state that has a uniform conductance,  $47.5 \pm 0.5 \text{ pS} \pm \text{s.d.}$ , in the conditions of Fig. 1, and cease conducting abruptly and completely<sup>15</sup>. Three examples of these 'typical' channels are shown in the upper trace of Fig. 1. By recording the occurrence of many single channels, we have been able to observe a small but well defined fraction of channels that have novel, atypical properties. The middle trace of Fig. 1 shows, for example, a weakly conducting 'mini' channel (4.6 pS) turning on at point A. At point B the mini channel abruptly becomes more conductive, with a conductance (47.9 pS) characteristic of typical channels, and at point C this channel ceases to conduct. The lower trace of Fig. 1 illustrates that channel conductance may also spontaneously decrease. On this trace a mini channel of high conductance  $(45.2 \,\mathrm{pS})$  turns on at point A, at point B the conductance decreases abruptly and spontaneously to 6 pS and after returning to 45.2 pS at C, the channel turns off at D. We considered whether such traces could merely be the coincidental occurrence of two transitions (such as a turn-on and a turn-off) in the same sampling interval. By using very thin mono-olein/squalene bilayers<sup>15</sup> (and thus maximizing the singlechannel lifetimes), applying only small amounts of gramicidin and sampling rapidly compared with the transition rate, we were able to minimize the possibility of two transitions occurring in the same sampling interval. Twenty-six spontaneous state changes were observed in a contiguous, prospectively studied set of data lasting  $8.25\ h$  ( $8.9\times10^5$  sampling intervals) and containing 424 channels. In our conditions of measurement, the probability that all 26 events resulted from coincidental transitions is <1 in  $10^{41}$ . Therefore we must be observing conductance changes in the same channel. Clearly the same gramicidin channel can assume multiple conductance states.

The diminished conductance of the mini state must arise from a spontaneously increased barrier to ion transport or increased binding of ions in the pore. If such a change occurred at the centre of the pore, the I-V relationship should be symmetrical, as it is for the main channel (Fig. 2a). However, if this change occurred near either end of the pore, an asymmetrical I-V relationship  $^{16,17}$  would be expected. We have found that I-Vrelationships of mini channels are frequently asymmetrical, as illustrated in Fig. 2. Curve a shows the I-V relationship for a single typical channel recorded for 19 sweeps of the I-V curve. Before turning off, the channel converted to a mini channel and the I-V relationship was recorded for six sweeps of the membrane potential (curve b). Curve c shows 11 sweeps of the I-V curve for a single mini channel which did not change state during its lifetime. The broken line is drawn as a reference to demonstrate the asymmetry of the mini channels compared with the symmetry and linearity of the I-V curve of typical channels (curve a).

Although the spontaneous changes between conductance states are infrequent, the occurrence of mini channels which do not change states is rather frequent. This remains the case after extensive purification 6,18-20 and de novo synthesis 20,21 of gramicidin A. Figure 3 shows the relative frequency of minis in the conductance transition histogram. Of the 354 channels that occurred during the experiment, 199 (56%) were mini channels. In other experiments the fraction of minis ranged from 22% to

**Fig. 2** Single-channel I-V relationships for a typical channel, (a, 45.3 pS) and a mini channel into which it converted (c). Also shown is a mini channel which did not change states during its lifetime (b). Purified gramicidin A was added to a glyceryl-1-monoolein/squalene  $(50 \text{ mg ml}^{-1})$  bilayer and a triangular voltage wave (0.5 Hz) applied. Current and voltage were filtered at 100 Hz and sampled simultaneously  $300 \text{ times per s. Baseline-cycle currents were subtracted digitally from currents in cycles where a single channel was conducting and the result plotted against the corresponding measured voltage. The broken reference lines have slopes of <math>22.7 \text{ pS}(c)$  and 3.8 pS(b). 1 M KCl,  $p \text{H} \sim 5.6$ ,  $23 \pm 1 ^{\circ}\text{C}$ .

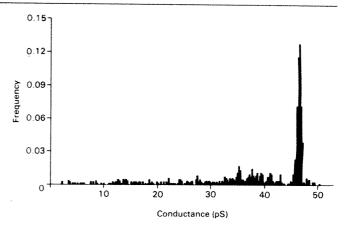

Fig. 3 Histogram of single-channel conductances using HPLC-purified gramicidin A. The sharp peak has a conductance of  $46.0\pm0.3$  (s.d.) pS and contains 44% of the transitions. The remainder are minis which we define as those with a conductance more than two standard deviations below the mean of the main gaussian peak. Glyceryl-1-monoolein (50 mg)/hexadecane (1 ml, Aldrich Gold Label), 1 M KCl,  $pH \sim 5.6$ , 0.1 V,  $23\pm1$  °C.

50%, varying within the expectations based on Poisson statistics. The conductance of minis has a broad distribution over 0-45 pS without any sharply defined features. This implies a profusion of different states whose probabilities of occurrence are roughly the same. The low frequency of spontaneous changes between conductance states ( $<0.0013 \, s^{-1}$ ) indicates that the different states correspond to stable conformations that are separated by large free-energy barriers. A rudimentary calculation, based on absolute rate theory, gives a barrier height of  $\ge 21 \, \text{kcal mol}^{-1}$ .

We found that the rate of channel opening for minis was directly proportional to the rate of channel openings for typical channels over a 1,000-fold range. This indicates that the turn-on frequencies for mini channels and typical channels depend in the same way on membrane gramicidin concentration. As channel turn-on frequency is proportional to the square of gramicidin concentration<sup>16,22,23</sup>, both mini and typical channels must result from the association of two monomers. Thus minis cannot be membrane-spanning monomers, laterally associated trimers or tetramers, or trimers or tetramers in series<sup>6</sup>.

We also found that the mean lifetime of minis does not differ from that of typical channels in either GMO-squalene (40-60 s) or GMO-hexadecane (2-3 s) bilayers. The similar lifetimes of minis and typical channels indicate that (1) minis are not normal channels in thicker patches of membrane<sup>6</sup> and (2) the mini channel structure could not differ greatly from the  $\beta$ -helical<sup>4,10</sup> head-to-head<sup>24,25</sup> dimer structures of typical channels. Were minis of a radically different conformation<sup>26,27</sup> (such as a parallel helix, as proposed by Veatch<sup>26</sup>), their lifetime should also be different from that of the typical channels because a different number of hydrogen bonds must be broken to dissociate such a dimer. Similar arguments rule out other variations of the helical pitch<sup>4</sup> of dimers at the head-to-head junction which would require a different activation energy for dimer dissociation.

Three classes of mechanism for the formation of mini channels would seem consistent with our observations. First, minis could result from the influence of an external factor on the channel, for example a dipolar or charged moiety<sup>16,17</sup> binding tightly to the external surface of one end of the pore and thereby reducing its ion conductance. Second, minis could result from defects in the  $\beta$ -helical structure of the peptide backbone away from the head-to-head junction, as suggested by structural studies<sup>11</sup> indicating that the presence of an ion in the channel may alter the pitch of the backbone helix. Finally, as proposed by Urry et al.<sup>28</sup>, changes in the positions of the side chains, particularly the large tryptophan and leucine R groups, could decrease channel conductance asymmetrically. These side-chain

effects could be mediated by changes in the equilibrium positions of the backbone carbonyls, by changes in the local electric field or the electron-donating capacity of carbonyls, or by changes in the libration energy 10,28 of the protein backbone. If conductance states are determined by side-chain positions, then it is reasonable to speculate that dipolar or reactive residues could couple these states to the electrical potential and/or the presence of agonist molecule, resulting in electrically or chemically gateable channels.

We thank Drs R. E. Koeppe and Dan Urry for gifts of purified gramicidin A, and Drs Wayne Giles, Ron Waldbillig and Don McBride for their comments and suggestions. This work was supported by DHHS grants GM 26897 and HL 24820.

#### Lateral diffusion of lipids in sarcoplasmic reticulum membranes is area limited

#### Peter Laggner\*

Institut für Röntgenfeinstrukturforschung der Österreichischen Akademie der Wissenschaften und des Forschungszentrums Graz, Steyrergasse 17, A-8010 Graz, Austria

Scandella et al. used the technique of electron spin resonance to investigate lateral lipid diffusion in the membrane of sarcoplasmic reticulum from skeletal muscle. Their results suggested that lipids are free to diffuse within the plane of the membrane at rates comparable with those in isolated phospholipid bilayer systems of similar composition<sup>2-4</sup>. However, their study<sup>1</sup> was carried out at temperatures between 50 and 70 °C. I have therefore now carried out similar studies, but at physiological temperatures and using fatty acid analogue spin labels. My results show absence of spin-exchange interaction at spin label concentrations below 2-4 mol %. This suggests the existence of diffusion barriers in the plane of the membrane which separate the lipids into clusters containing, on average, about 50 phospholipid molecules.

n, Number of phospholipid molecules per bilayer cluster calculated from the concentrations at the break points in Fig. 1b. SR, sarcoplasmic reticulum.

Electron spin resonance (ESR) measurements were carried out between 20 and 40 °C using a stearic acid analogue label, 2-(3-carboxypropyl)-4,4-dimethyl-2-tridecyl-3oxazolidinoxyl ('5NS'; Syva). This type of spin label has been useful in estimating lateral diffusion rates in Escherichia coli membranes<sup>5</sup>. Its advantage over the phosphatidylcholine analogue used by Scandella et al.1 lies in the relative ease of its introduction into the membrane system, thus avoiding the controllable process of fusion between phosphatidylcholine vesicles and the membrane, which is likely to cause a major structural perturbation in the membrane region where it occurs. The obvious disadvantage of the stearic acid label lies in its structural difference from endogenous lipids.

The method is based on the notion that the collision of spin labels introduced into the fluid lipid phase of the membrane is controlled by diffusion. Since colliding free nitroxide radicals will undergo spin-exchange interaction causing broadening of the ESR lines<sup>2,3,6</sup>, the collision frequency can be monitored by linewidth measurement. Although quantitative evaluation in terms of diffusion coefficients must rely on certain specific assumptions about the diffusion model<sup>4.6</sup>, the observation of concentration-dependent line broadening unambiguously indicates the occurrence of label diffusion.

Figure 1 shows that, within the temperature range used, no concentration-dependent line broadening of the ESR spectrum was observed below certain critical spin label concentrations, indicating that no collisions take place up to these concentrations. Above these concentrations, the linewidth increased, as expected for diffusion-controlled spin label collisions. The same behaviour was found with a different stearic acid analogue label, 2-(10-carboxydecyl)-2-hexyl-4,4-dimethyl-3oxazolidinoxyl (12NS; Syva), while the methyl ester of 12NS showed the same linearly ascending stope at even the lowest concentrations (0.5 mol %).

By adopting the diffusion model and numerical factors described in detail by Sackmann et al.5, the diffusion constants calculated from the slopes above the critical concentrations (Table 1) correspond satisfactorily to the values determined previously for phosphatidylcholine spin labels<sup>1</sup>. This consistency strengthens the reliability of results obtained by stearic acid spin labels. Parallel experiments with extracted membrane phospholipids in aqueous dispersion have verified the fact that at these low concentration increments line broadening could indeed be measured. The slopes observed with the isolated lipid samples were only slightly higher than with the membrane system, confirming that, once diffusion control of collisions prevails, the diffusion rates are very similar in the two systems.

Quantitative evaluation of the hyperfine peaks in terms of the order parameter  $S_3$  and the isotropic coupling constant  $a'_N$  (refs 7, 8) have shown constant values of 0.68 and 14.6 respectively, up to label concentrations of 10 mol %. This eliminates the possibility that the observed absence of collisions is due to binding of the first added spin labels by protein. Therefore, to interpret these effects, I postulate the existence of diffusion barriers in the plane of the membrane separating individual clusters of lipids. Table 1 lists the size of these clusters estimated

<sup>\*</sup> Present address: European Molecular Biology Laboratory, Hamburg Outstation, c/o DESY, Notkestrasse 85, D-2 Hamburg, FRG.

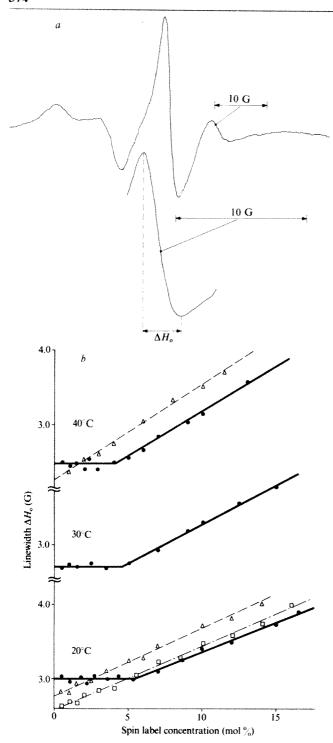

Fig. 1 a, Typical ESR spectrum from stearic acid analogue 5NS in sarcoplasmic reticulum membranes at label concentrations of 1 mol %, relative to total phospholipid (taken as molecular weight 750). Spectrometer settings were as follows. Field set 3,359 G; microwave power 10 mW; receiver gain  $5 \times 10^3$ ; modulation amplitude 0.5 G; recorder time constant 0.5 s; scan time 4 min. The central line was recorded in a scan range of 40 G to facilitate precise linewidth measurement. A Varian E 104-A X-band spectrometer with variable temperature control unit was used. Sarcoplasmic reticulum membranes were prepared according to previously documented methods 10,11 and studied within 48 h of preparation. Spin labels were introduced by gently shaking membrane suspensions, typically containing ~20 mg ml pholipids, under N<sub>2</sub> atmosphere in a glass tube containing the appropriate amounts of dry label deposited on the wall. b, Linewidths of the central ESR line of 5NS in sarcoplasmic reticulum membranes (●), isolated membrane phospholipid suspensions (△) and a sample of sarcoplasmic reticulum that had undergone 1 min ultrasonication ( ) using the 1-cm probe tip of a Braun Labsonic sonicator.

from the critical onset concentrations for line broadening. For simplicity, this calculation involves the assumption that the clusters are phospholipid bilayers, that is, contain twice the number of molecules as deduced from the critical concentrations.

At physiological temperatures, the clusters would contain, on average, 50 phospholipid molecules, which is about half the of phospholipids per molecule of (Ca<sup>2+</sup>+ number Mg<sup>2+</sup>)ATPase, the major integral protein constituent of the membrane. It could be speculated that this reflects the fraction of phospholipids that are not involved in forming an 'annulus' around the ATPase which, by definition, would diffuse at a considerably slower rate.

The above estimations imply uniform contributions to the measured linewidths by all spin labels. This is supported, at concentrations <5 mol %, by the absence of any free-label signal, indicating that all spin labels are incorporated into the membranes. Even above this concentration, the area under the subsequently gradually occurring free-label signal is only a minor fraction of the total and hence safely negligible for the present considerations. On the other hand, it cannot be excluded that a small number of spin label molecules are immobilized by binding to protein below the detection level. However, this also is negligible in relation to the concentrations relevant here.

Although it is premature to speculate on the detailed nature of the diffusion barriers, the finding that neither lipids alone nor ultrasonically perturbed membranes show these effects suggests that protein-protein interaction is probably involved. The observation that only the free stearic acid analogues and not the methyl ester are sensitive to this effect furthermore suggests that ionic interactions might be relevant in defining the limits of lipid diffusion. Note that the present results allow direct conclusions only to negatively charged lipids. Future experiments must show whether this also holds true for positive or zwitterionic lipids.

I thank Mrs U. Rakusch for technical assistance and Dr J. Suko for supplying several membrane samples. This work was supported under grant 3524 by the Österreichischer Fonds zur Förderung der Wissenschaftlichen Forschung.

#### Variant insertion element IS1 generates 8-base pair duplications of the target sequence

#### Shigeru Iida, Roberto Marcoli\* & Thomas A. Bickle

Microbiology Department, Biozentrum, University of Basle, Klingelberstrasse 70, CH-4056 Basle, Switzerland

Transposition in both eukaryotes and prokaryotes is characterized by the generation of short, direct duplications of the target DNA sequence at the integration site of the transposable element<sup>1</sup>. For example, the bacterial insertion sequence IS1, or

<sup>\*</sup> Present address: ISREC, Chemin des Boveresses, CH-1066 Epalinges s/Lausanne, Switzerland.

the IS1-flanked transposon Tn9, generates 9-base pair (bp) repeats during either transposition or cointegration  $^{2-8}$ . All the transposable elements so far sequenced are characterized by the presence at their ends, of a perfect, or near-perfect, inverted repeat sequence, which is ~30 bp long and is thought to be important for recognition by enzymes during transposition. While studying IS1-mediated cointegration  $^{9-12}$ , we found an IS1 carrying a single base pair change in the terminal inverted repeat sequence. We now report that it generates 8-bp duplications of the target sequence, a finding which confirms the importance of the inverted repeat for transposition and which, because one end only of the IS1 is changed, has implications for the mechanism of transposition by IS1.

We have characterized four pBR325 derivatives carrying IS I, all of which resulted from segregation of cointegrates between pBR325 and plasmid P1, which contains an IS I element 11-13 (Fig. 1). The sites of insertion and the orientation of the IS I in these different derivatives have been described previously 11,12, and the sequencing strategy used is shown in Fig. 2.

Figure 3 shows the results of the DNA sequence analysis around the junctions of IS1 and pBR325. In each plasmid, the IS1 had integrated at a different position within a 300-bp region of pBR325 between coordinates 4,134 and 4,411 (ref. 14). Two of the plasmids (pSHI211 and pSHI212) carried the 9-bp duplications of target sequence previously reported for IS1<sup>2-8</sup> but the other two (pSHI213 and pSHI214) had only 8-bp

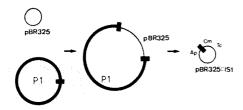

Fig. 1 The formation of transpositional cointegrates. Phage P1 was induced in P1-lysogenic Rec<sup>+</sup> bacteria containing pBR325, which codes for resistance to ampicillin (Ap), chloramphenicol (Cm) and tetracycline (Tc) <sup>14,31</sup>, and cointegrates were isolated as specialized P1 transducing phages. Their structure is shown in the centre of the figure: the P1 genome (thick line) has integrated into the pBR325 (thin line) and is flanked by direct repeats of the IS1 element resident on the P1 genome (bar). Subsequent resolution of these cointegrates in Rec<sup>+</sup> cells yields a pBR325 derivative carrying a single copy of IS1<sup>11,12</sup>.

duplications. The IS element of the latter two has a G to T transversion at position 757, 12 bp from the end of the element, and no other alteration within 50 bp of the end when compared with the canonical sequence<sup>3.15,16</sup>. The same alteration has also been found in one of the flanking IS 1s of  $Tn9^8$ . There seems to be a good correlation, in our experimental conditions, between the alteration in the inverted repeat of IS 1 and the ability of the element to generate 8-bp repeats.

The transposition characteristics of the variant IS I seem very similar to those of IS I itself. For example, in both cases the preferred sites for IS I integration are A+T rich<sup>5-8,17-19</sup> and both elements show a strong preference for inserting in sites that have a G-C base pair at each end of the target sequence to be duplicated<sup>8</sup>. The variant IS I stimulates the formation of deletions, as does the wild type, and transposes with a slightly higher frequency I 1,12.

IS1-mediated transpositional cointegrations have been observed in various experimental systems  $^{7,9,11,12,20}$ . As only one of the two parental plasmids originally contained an IS1 and the resulting cointegrates carry two IS1s at the junction of the replicons (Fig. 1), one can assume that the IS1 duplicates during

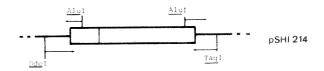

Fig. 2 Sequencing strategy for the variant IS1 ends. IS1 is drawn as a box and the flanking DNA sequences as a horizontal line; the vertical line within the box shows the orientation of IS1 and indicates the position of the single Ps1 site. Plasmids pSHI213 and pSHI214 had IS1 integrated into pBR325 at locations 4,404–4,411 and 4,134–4,141 respectively, and were sequenced as indicated by arrows. The other two plasmids, pSHI211 and pSHI212, had IS1 integrated at positions 4,202–4,210 and 4,248–4,256 respectively, and the ends were sequenced using the AluI sites of IS1. DNA sequencing was done using the method of Maxam and Gilbert<sup>32</sup>.

the process. If this is the case, the IS1 elements carried by the four pBR325 derivatives that we have analysed ought to have the same DNA sequence as the IS1 of P1. However, we find that two of the four carry an alteration. The possibility that the P1 parental phage carried heterogeneous IS1s is less likely because the cointegrates were isolated from fresh lysogens derived from a single plaque. Alternatively, a chromosomal IS1 may first have transposed into pBR325 and the cointegrates then have arisen by reciprocal recombination between the IS1 acquired by pBR325 and the IS1 of P1; such a pathway has recently been demonstrated in Rec<sup>+</sup> cells<sup>12</sup>. The most likely explanation is that two of the four cointegrates studied were formed by this pathway while the other two were formed by the IS1 duplication process. The same G to A transversion has been found in the flanking IS1 of Tn9 carried on  $\lambda cam1^8$  and this Tn9 originally derived from P1Cm0, which has Tn9 inserted within the IS1 of P1 (refs 13, 21-23). Therefore, the variant IS1 probably comes from the P1 genome.

The recently proposed models for transposition fall into two groups differing in the mechanism of transposition initiation. In group I models, only one end of the IS element is ligated to the target sequence at the initiation step $^{24-26}$ , whereas group II models predict that both ends of the IS element are ligated $^{27.28}$ . A cointegrate is a necessary intermediate in group II models whereas it is a by-product in group I models. Evidence supporting transposition of IS 1 by a group I mechanism comes from the study of IS 1-mediated cointegrates. Their formation seems to be less frequent than transposition, but once formed they are

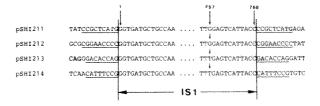

Fig. 3 DNA sequence of the ends of IS1 and flanking sequences. The ends of the IS1 are delineated by vertical lines. Duplicated plasmid sequences are underlined. Arrows indicate the position of the variation in the terminal inverted repeat of IS1 carried by pSHI213 and pSHI214. IS1 coordinates are from ref. 15.

stable, even in recombination-proficient cells<sup>7,10-12</sup>, which argues that they are not intermediates in transposition. This contrasts with some other transposons, such as Tn3, where the cointegrates are unstable 28-30; such transposons probably use a group II mechanism. Our observation that an alteration in one end only of IS1 changes its transposition characteristics also favours a group I mechanism. In this respect, it is interesting that the Tn9 with the same base alteration has been shown to generate 9-bp repeats<sup>4,8</sup>. It is unlikely that the repeat generated depends on whether the process is transposition or cointe-

gration. The end of the IS element chosen to initiate transposition may be dictated not only by the sequence of the IS element itself, but also by sequences in the donor DNA molecule, perhaps the recognition sequences in the donor that were used when it previously acquired the IS element.

#### Promoters in the E. coli replication origin

#### Heinz Lother & Walter Messer

Max-Planck-Institut für molekulare Genetik, Abt. Trautner, Ihnestrasse 63/73, D-1000 Berlin 33, FRG

Chromosomal replication in Escherichia coli initiates at a particular sequence in the parental DNA called the origin of replication (oriC) and proceeds bidirectionally. Initiation requires the interaction of various factors at a given time within chromosomes have been constructed<sup>4-6</sup> and partially sequenced<sup>7,8</sup> whose replication sequenced<sup>7,8</sup> whose replication proved also to be dependent on a rifampicin-sensitive host function in addition to the products of several initiation genes<sup>6,9</sup>. Using one of these mini-chromosomes, pCM959<sup>6,8</sup>, we have searched for promoters in and close to oriC to elucidate the role of RNA polymerase in the initiation of replication. We have found, by in vitro transcription experiments and RNA sequencing, that the DNA segment required for the start of bidirectional replication in E. coli contains two promoters arranged back-to-back. The location and arrangement of these promoters suggest an involvement in the initiation of replication.

Several complementary techniques were used to identify promoters likely to be involved in the initiation of replication. First we surveyed for promoters by mapping RNA polymerase binding sites present on pCM959 using electron microscopy. Three RNA polymerase binding sites, at nucleotide positions  $267 \pm 61$ ,  $791 \pm 55$  and  $3,991 \pm 68$  of pCM959, mapped close to or within oriC; details will be published elsewhere

We used an in vitro transcription assay to determine the direction of transcription, the precise location of the transcription starts and the relative efficiencies of these promoters, which presumably have different functions. Various restriction fragments from pCM959 encompassing the three RNA polymerase binding sites of interest were used as templates for

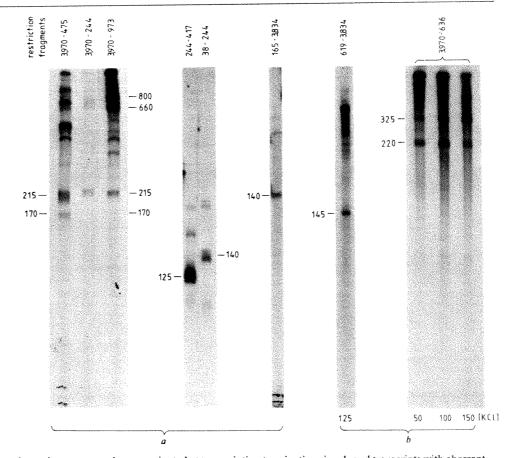

purified RNA polymerase. The products of such reactions are

Figure 2 shows the alignment of transcripts that end at the termini of these restriction fragments (run-off transcripts). For example, using the HaeIII fragment (position 3,970 to 636) as template, transcripts are obtained that are 220 and 325 nucleotides long (Figs 1b, 2). When this fragment is cleaved with Hhal (position 475) or HindIII (position 244), the 220 (215)-nucleotide transcript is still present, but instead of the 325-nucleotide transcript, a shorter length of 170 nucleotides is found, or, in the case of HindIII cleavage, the transcript is missing entirely (Figs 1a, 2). A 125-nucleotide transcript, however, is obtained if the HindIII-XhoI fragment (position 244 to 417) is assayed. The results obtained with the different fragments (Fig. 2) suggest that the RNA polymerase binding site observed at position  $267 \pm 61$ is in fact due to two promoters situated back-to-back, which we designate Pori-1 and Pori-r. According to this analysis the RNA origins should be located at position 170±7 for Pori-1 with counterclockwise transcription, at position 310 ± 10 for Pori-r with clockwise transcription, at position  $765 \pm 7$  for the binding site at position  $791 \pm 55$  with counterclockwise transcription, and at position  $3,980 \pm 10$  for the binding site at  $3,991 \pm 68$  with counterclockwise transcription.

To determine precisely the transcriptional starts, and to confirm the alignment, various 5'-end-32PO4-labelled transcripts obtained from restriction fragments encompassing both origin promoters were subjected to RNA sequence analysis 11-14. The RNA sequences were then compared with the DNA sequence. Transcripts originating from Pori-1 started mainly with C at position 166 (Figs 3, 4). Transcripts originating from Pori-r started mainly with A at position 323 (Figs 3, 4); some transcripts from Pori-r, however, started with G at position 313 (complete sequencing data will be published elsewhere).

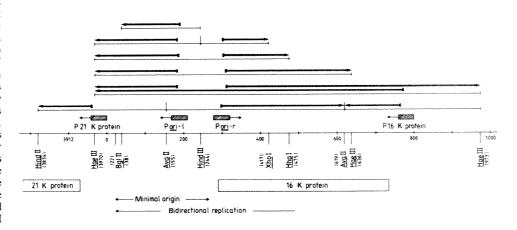

The directions of transcription determined for the promoters outside oriC agree with those inferred from the pCM959 nucleotide sequence (Fig. 3). These two promoters are followed by a Shine-Dalgarno sequence<sup>15</sup> within the postulated distance<sup>16</sup> of an open reading frame for proteins with molecular weights (MWs) of 16,000 (ref. 7) and 56,000, respectively (Fig. 3). The function of the 16,000-MW protein is unknown but it does not seem to have a major effect on minichromosome

ctrophoretic analysis of synthesized by purified E. polymerase holoenzyme rious restriction fragments passing oriC. The transcripxperiments were carried out in nal volume of 200 µl with 0.05μg purified DNA fragment and -15 µg RNA polymerase (85 mol RNA polymerase per mol DNA fragment<sup>28</sup>) in 40 mM Tris-HCl pH 8.0, 10 mM MgCl<sub>2</sub>, 4 mM dithiothreitol, 400  $\mu$ M ATP and pH 8.0. GTP, 100  $\mu$ M CTP and UTP+50-100  $\mu$ Ci[ $\alpha$ - $^{32}$ P]UTP with a, 50 mM KCl and 100  $\mu$ g ml<sup>-1</sup> heparin<sup>29,30</sup> or b, 50, 100 or 150 mM KCl (ref. 28). Reaction mixtures were preincubated for 10 min at 37 °C in the absence of a, UTP, CTP and heparin, or b, MgCL<sub>2</sub> (ref. 28). The complete reaction mixture was incubated for 20 min at 37 °C and the reaction stopped by addition of phenol. Samples were precipitated with ethanol, dissolved in 50% formamide, treated for 2 min at 100 °C, and subjected to electrophoresis in 8% (a) or 10% (b) polyacrylamide gels containing urea<sup>31</sup>. Numbers above the tracks specify the coordinates of the restriction fragments. Numbers alongside major transcripts represent their size in bases. 32Plabelled DNA fragments served as

length standards. Transcripts having no size assignments are those terminated at transcription termination signals and transcripts with aberrant electrophoretic behaviour, as evidenced by the nucleotide sequence of their 5'-terminal portions.

Fig. 2 Alignment of transcripts obtained from restriction fragments containing oriC and/or adjacent DNA segments. According to the length determination specified in Fig. 1, major transcripts (thick lines) were arranged by aligning their 3 ends with the ends of restriction fragments (thin lines). The positions of the promoters are indicated by cross-hatched boxes. Arrows indicate transcription directions. Numbers next to restriction sites within the physical map specify their coordinates. The open boxes beneath the physical map specify the coding regions of proteins. Both the limits of the minimal origin<sup>23</sup> and the region required for bidirectional replication<sup>24</sup> are shown. The *HaeIII* (636) site is only present in a derivative of pCM959.

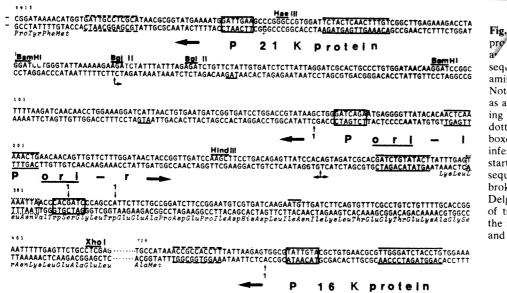

replication<sup>17</sup>, even though its coding region overlaps partially with that of transcripts from Pori-r. The 56,000-MW protein is a fusion product of a 21,000- and a 35,000-MW partial peptide as its coding region traverses the point of circularization of pCM959 (data not shown). The 21,000-MW partial peptide may be the beginning of a 70,000-MW protein designated gid, which was mapped in this region<sup>17</sup>. Both a 16,000- and a 70,000-MW protein have been seen after infection of minicells carrying the  $\lambda$  repressor-overproducing plasmid pGY101<sup>18</sup> with  $\lambda$  vectors into which different minichromosomes were inserted (unpublished results), and in cells carrying minichromosomes<sup>19</sup>. Both these promoters were also demonstrated in vivo<sup>19</sup>.

Although these observations suggest a linkage between transcription and translation for the two promoters outside oriC, a

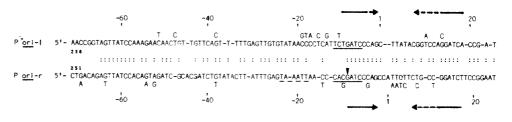

coupling of these two processes for the two oriC promoters seems unlikely. Nonsense codons are present in all reading frames, and the longest possible peptides which can be deduced from the nucleotide sequence downstream of Pori-1 and Pori-r are 27 amino acids long (130-50) and 55 amino acids long (351-525), respectively (Fig. 3). Such peptides have so far not been identified. The origin promoters seem to be as active in vitro as the 16,000-MW protein promoter and far more active than the 21,000-MW partial protein promoter, which expresses transcripts that are barely above background. Therefore we suggest that these promoters are also used in vivo, but for a purpose other than protein biosynthesis.

When the nucleotide sequences of the two origin promoters are compared, we observe extended sequence homologies

pro sequ amino Note that n. as a transcript a ing Pribnow box dotted line. † Transc. boxes indicate Pribnow . inferred from the transcra, starts<sup>20</sup>; lines above and below t<sub>1</sub>, sequences represent -35 regions<sup>20</sup>; broken lines indicate Shine-Delgarno sequences<sup>15</sup>.  $\rightarrow$ , Direction of transcription;  $\leftrightarrow \leftarrow \uparrow$ , limits of the minimal origin segment<sup>23</sup>. Start and stop codons downstream of Poril and Pori-r are underlined.

Fig. 4 Comparison of origin promoters of E. coli and S. typhimurium. The sequences of the noncoding strands starting at base 238 and 251, respectively, are compared. Numbers above below the sequences refer to nucleotide positions relative to the transcriptional start. The 'secondary' Pribnow box occurring in Pori-r is marked by dashes; ▼ represents its

corresponding 5' start nucleotide. The corresponding S. typhimurium sequence 21 is shown above or below the E. coli sequence only where there are sequence differences. : indicate identical bases in the two E. coli promoter sequences. Note that most changes within the promoter sequences are found in regions which are also more variable in other promoters. The changes are located between the Pribnow boxes (underlined regions) and around base -20 (ref. 20). Other changes occur within the loop of a putative operator structure indicated by inverted arrows.

around position -50 to -70 and close to the transcription starts (Fig. 4). The region preceding the actual promoter sequence is known to be important for positive control in the lac, gal and other systems<sup>20</sup>. This sequence homology is also evident when these regions are compared with the corresponding segment in the Salmonella typhimurium origin (ref. 21; Fig. 4) and with the other origins of Gram-negative bacteria so far sequenced, for example Klebsiella pneumoniae, Enterobacter aerogenes and Erwinia carotovora<sup>22</sup>. Thus an attractive hypothesis is that such RNA synthesis occurs in all these Gram-negative bacteria and that it is subject to positive control in all cases. The second conserved sequence homologies are close to the transcription starts. These regions of homology can form imperfect palindromes and may therefore represent sites of interactions, occurring on both promoters, with a hypothetical repressor.

The minimal DNA segment required for origin function extends from position 22 to position 267 (ref. 23; Fig. 3) whereas oriC, the origin required for bidirectional replication, has been shown to extend beyond position 417 (ref. 24). Pori-1 is thus completely contained in the DNA segment that is sufficient for leftward unidirectional replication. Pori-r is located in that part of oriC which is, in addition, required for bidirectional replication. This arrangement suggests that the origin promoters are responsible for the synthesis of RNA primers required for the inception of the leading DNA strands. However, we cannot rule out the possibility that Pori-1 and Pori-r promote, together or exclusively, transcriptional activation<sup>25</sup> or that one or both transcripts have a regulatory role similar to that of the short RNA molecules found in some plasmid systems<sup>26,2</sup>

# Molecular dynamics of hydrogen bonds in bovine pancreatic trypsin inhibitor protein

#### **Michael Levitt**

Department of Chemical Physics, Weizmann Institute, Rehovot, Israel

Molecular dynamics simulations starting from the X-ray structure<sup>1</sup> of bovine pancreatic trypsin inhibitor protein (BPTI) reveal that the different hydrogen bonds observed in the X-ray coordinates have different stabilities as indicated by the mean lengths and length fluctuations. The most stable hydrogen bonds involve the hydrogen atoms observed to exchange most slowly with solvent in NMR experiments<sup>2</sup>, and to have the shortest lengths in the X-ray structure. This agreement between calculation and experiment suggests that molecular dynamics simulations can complement X-ray studies by providing reliable information about the rates and pathways of conformational changes about the mean positions observed in protein crystals.

The results of dynamics simulations depend on the molecular potential energy from which the forces acting on the atoms are calculated. As all force calculations on proteins<sup>3-5</sup> use an approximate empirical potential energy function and omit the thousands of surrounding solvent molecules, it is essential to check the results quantitatively before using such theoretical

methods to calculate quantities that cannot be measured. Two observable properties of globular proteins seem particularly well suited to such a test: (1) the amplitudes of atomic vibration available from the highest-resolution X-ray studies can be compared with the amplitudes computed from a dynamics run; and (2) the rates at which hydrogen atoms in the protein exchange with deuterium atoms in solution, as measured by <sup>1</sup>H NMR, can be compared with the computed fluctuations in the hydrogen bond lengths. Northrup et al. <sup>6</sup> have shown that the observed and calculated atomic vibration amplitudes yield similar pictures for the atomic mobility in the protein ferrocytochrome c.

Here I analyse the results of molecular dynamics simulations on the protein BPTI in terms of the length fluctuations of hydrogen bonds. BPTI is the obvious choice for this study as the rates of exchange of individual protons are not available for other globular proteins<sup>2</sup>. In the calculation, the equations of motion in the protein force field used previously<sup>5,7</sup> are solved by the Beeman<sup>8</sup> method of numerical integration with a time step of  $2 \times 10^{-15}$  s. Rapid equilibration is achieved by starting from a completely relaxed structure generated by extensive conjugate gradient minimization<sup>5</sup> (up to 3,000 energy evaluations) from the X-ray structure and then gradually increasing kinetic energy by small random impulses to give an equilibrium velocity distribution (gaussian) with no local 'hot spots'.

The mean lengths and length fluctuations of hydrogen bonds calculated from a 56-ps molecular dynamics simulation (see Table 1) are insensitive to the part of the trajectory from which they are calculated (correlation coefficient of mean lengths in MD1 and MD2 is 0.98), indicating that the trajectory is well equilibrated for calculation of these quantities. The different hydrogen bonds in the structure show systematic differences in mean lengths and length fluctuations allowing all 24 hydrogen bonds in Table 1 to be classified as 'stable', if the mean length (the O—H distance) is <1.90 Å and the r.m.s. length fluctuation

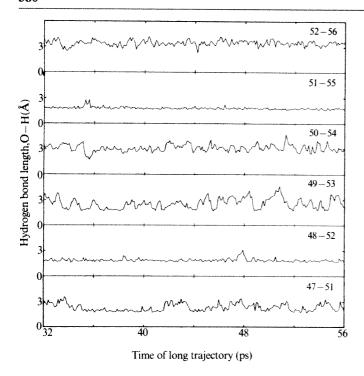

Fig. 1 The time variation of the six O—H distances of the peptide hydrogen bonds observed in the C-terminal  $\alpha$ -helix of BPTI during the period of 32-56 ps of the trajectory. A well-formed hydrogen bond has a length of 1.7-2.2 Å.

(amp.) < 0.22 Å (marked 'S' in Table 1), or 'unstable' otherwise (marked 'U'). Comparison with the experimentally determined X-ray lengths<sup>1</sup> shows that the 'stable' hydrogen bonds are significantly shorter: 15 of the 16 X-ray lengths <2.07 Å correspond to hydrogen bonds defined as stable by the independent criteria given above. Comparison with the <sup>1</sup>H proton NMR exchange rates measured for peptide protons<sup>2</sup> shows that the 'stable' hydrogen bonds have significantly slower proton exchange rates: 14 of the 15 most slowly exchanging protons found experimentally correspond to stable hydrogen bonds (S in Table 1).

This agreement between the classification of the 24 hydrogen bonds on the basis of the dynamics simulation and either the X-ray lengths or the NMR exchange rates is highly (99.99%) significant. If the 24 hydrogen bonds were to be randomly assigned as 'S' or 'U' subject to the requirement that there be exactly 15 'S' assignments, there would be 24!/(15! 9!) distinct arrangements. One of these would match the NMR exchange rates exactly and 9 × 15 would have two mismatches, as is found here. The probability of getting chance agreement as good as that seen here is  $(9 \times 15 + 1)/(24!/(15! 9!)) = 136/1,307,504 =$ 0.0001.

Despite this good agreement, the correlation between the mean lengths (or length fluctuations) and the actual exchange rates of individual hydrogen bonds is poor (for example, both Phe 33, O-Arg 33, H and Thr 11, O-Gly 36, H are correctly classified as stable but have exchange rates that differ by five orders of magnitude). Thus although the calculation can successfully predict which of the hydrogens will exchange slowly, it cannot predict the actual exchange rates. This is to be expected as hydrogen exchange occurs on the time scale of minutes and depends on many factors besides the stability of the hydrogen bond, including local unfolding, solvent penetration and catalysis by neighbouring groups.

Why are certain hydrogen bonds unstable as measured by the three independent criteria of dynamics simulation, X-ray lengths and NMR exchange rate? One explanation is that the

potential energy of certain hydrogen bonds is high (less favourable) due to local conformational strain. Another is that certain hydrogen bonds fluctuate more to increase their conformational entropy and so reduce the free energy of the system. The entropy gained from larger fluctuations depends on the density of packing around the hydrogen bond in question: if there is no space to move into, there is nothing to be gained from large fluctuations. Support for this idea comes from the accessibilities of the bonds (calculated as the sum of the static accessible surface areas of the O and N atoms in the X-ray structure): 5 of the 9 'U' hydrogen bonds in Table 1 are exposed (3, O-7, H =  $8.3 \text{ Å}^2$ ; 36, O-16, H =  $3 \text{ Å}^2$ ; 24, O-28, H =  $0.3 \text{ Å}^2$ ; 49, O-53, H =  $7.2 \text{ Å}^2$ ; and 50, O-54, H =  $37.8 \text{ Å}^2$ ) whereas only 2 of the 15 'S' hydrogen bonds are exposed (48, O-52, H =  $7.7 \text{ Å}^2$ and 24, OD1-26,  $H = 9.8 \text{ Å}^2$ ).

Figure 1 shows the time variation of the six peptide hydrogen bond lengths in the C-terminal  $\alpha$ -helix. The two stable hydrogen bonds (Ala 48, O-Met 52, H and Cys 51, O-Cys 55, H) vibrate mostly about the length value of 1.8 Å, but occasionally show increases in length of up to 3 Å for periods of  $\sim 0.5$  ps; these fluctuations do not involve the correlated breaking of hydrogen bonds adjacent along the  $\alpha$ -helix. The four unstable hydrogen bonds (Ser 47, O-Cys 51, H; Asp 49, O-Arg 53, H; Asp 50, O-Thr 54, H; and Met 52, O-Gly 56, H) show larger length fluctuations, but a good hydrogen bond is sometimes formed for a few picoseconds. The same type of dynamic behaviour is seen for the other hydrogen bonds and for other periods of the trajectory.

Discussion of the broad range of rates with which protons exchange in globular protein has in the past focused on how the particular groups contact the solvent 10-12,13. My study emphasizes another factor showing that the intrinsic stability of different hydrogen bonds differs and that the stable hydrogen bonds exchange more slowly.

This work differs from previous studies of BPTI dynamics<sup>3,4</sup> in two important respects. (1) I allow hydrogen bonds to be formed between all oxygen and hydrogen atoms that are close together in space. As the previous studies used a fixed list of hydrogen bonds taken from the X-ray data<sup>1</sup>, questions concerning hydrogen bond fluctuations could not be answered. (2) I use a different potential energy function, initially calibrated on the observed unit cell parameters of hydrocarbon, amide and amino acid crystals and then tested for its ability to give an equilibrium conformation close to the observed X-ray structure<sup>5</sup>. The present simulations do, however, have a serious shortcoming in the omission of the thousands of water molecules surrounding the protein molecule: 2,700 water molecules would have to be included to give a 0.02 M solution (very concentrated by experimental standards), increasing the computer time for one time step by a factor of ~10. This more realistic calculation is now in progress.

This work was partially supported by NSF award PCM-7808029. I thank Professor F. H. C. Crick for encouragement and critical discussion, and Dr R. Feldmann for making a film of the trajectory.

Volume 9 and a New Revised Edition in the well established series:

# HEISINI

edited by T.S. Work and R.H. Burdon (formerly edited by T.S. Work and E. Work)

#### Volume 9 by G. Allen

#### Sequencing of **Proteins and Peptides**

1980 xiv + 322 pagesUS \$29.75/Dfl. 61.00 (paperback) ISBN 0-444-80254-1 US \$79.50/Dfl. 163.00 (hardback)

The purpose of this monograph is to provide in one volume detailed descriptions of the techniques used in the determination of amino acid sequences of proteins by manual methods, together with a discussion of the theoretical background.

Major advances in the field have necessitated a high degree of selectivity, but references are given to alternative methods which may occasionally prove useful.

This book is a worthy contribution to an excellent series, and for scientists working in this area it will be an invaluable aid.

#### Volume 1, Part III 2nd Revised Edition **Immunochemical Techniques** for the Identification and **Estimation of Macromolecules**

#### Reviews of previous edition

"This is a splendid little book... It is rational and lucid and attractively laid out.' Chemistry and Industry

The rapid expansion in the field of immunochemistry has necessitated the publication

of a fully revised 2nd edition of the present manual. The aim of this book is to present practical advice on application of the rapidly expanding mass of data on immunochemistry, and more specifically to examine the possibilities of employing immunological microtechniques in histological biochemical analuses

Several chapters i.e. those dealing with lectins, HLA-antigens and with the application of crossed immunoelectrophoresis for characterization of membrane proteins, have been extensively revised and extended. Furthermore, new chapters dealing with the complement system, enzyme immuno-assay systems, immunofluorescence methods and immunoadsorbent techniques have been added and the recent developments in the methodology already presented in the first edition have been included.

This fully revised edition will prove invaluable as a practical aid to biochemists using the techniques of immunochemistry in their research.

#### The Quest for Extraterrestrial Life

A Book of Readings

by G. Goldsmith

This book contains selections of thought on the possibility of extraterrestrial life. With such a long stretch of time, and with so many possible sites for life in the universe, it might seem reasonable that life of all possible varieties must have appeared somewhere. This view has indeed held the majority — with important exceptions — so long as the Earth has not been considered unique. But the forms that life may take, and the ways in which we might find life elsewhere, or talk with other civilizations, have provoked a continuing debate, with no immediate resolution in sight.

Contents: Foreword by Sir Fred Hoyle; Preface; Historical Perspective; The Origins of Life; The Search for Life in the Solar System; Intelligent Life Outside the Solar System?; Optimists and Pessimists; Bread on the Waters; Bibliography; Index.

#### **Carbon Cycle Modelling SCOPE 16**

edited by **B. Bolin**, Department of Meteorology, University of Stockholm, Sweden

In view of the complex character of the carbon cycle, it is essential that all relevant data are used to develop and test more advanced models for the best possible prediction, and that this is co-ordinated on an international level. With this goal in mind, the Scientific Committee on Problems of the Environment, SCOPE, initiated a workshop on global carbon cycle modelling. The present volume is the outcome of the workshop, which united many world specialists in the field. Their work provides a survey of the current status of research and the most commonly used models to describe the global carbon cycle. The view is expressed that more detailed models of the oceans and terrestrial biota are needed for the development of accurate forecasts of the level of atmospheric carbon dioxide, and basic considerations for achieving this are outlined.

#### River Basin Planning: Theory and Practice

edited by S.K. Saha and C.J. Barrow, both of Centre for Development Studies, University College of Swansea

The contributing authors to this volume are experts drawn from different backgrounds, representing both academics and practitioners of planning. A unique feature of the book is that the case studies on which it is based are drawn mainly from the Third World, where the whole question of planning schemes is of paramount importance. The papers presented seek to highlight the past and present problems and to provide guidelines towards more effective implementation of river basin planning programmes in the future.

# **BOOK REVIEWS**

# Environmental impact re-assessment?

#### **David Pearce**

THE current fashion for environmental impact assessment (EIA) is partly explained by the continuing force of the environmental protection movement in Western countries. That movement is now under severe pressure from economic recession, and there are signs that impact assessments themselves will play a decreasing role in planning and development. Certainly, this is the message that emerges from the USA, where the emphasis is switching back to the costs of environmental protection. This reverse swing, no sign of which is even hinted at in the two volumes under review, is both unfortunate and misguided. But the environmental movement itself bears some of the responsibility. In their indecent rush to find an approach (some might say any approach) to the integration of environmental factors with the social and economic dimensions of development. environmentalists have produced a jumble of methodologies all too few of which have any rational grounding.

In essence, an EIA should identify all environmental and social impacts from a development. It may then leave them qualitatively recorded, or go further and measure them in physical terms or as "scores" reflecting a judgement of whether that impact is good, bad, moderate or serious. Neither Project Appraisal and Policy Review, which is a collection of essays on the state of play in EIA, nor Environmental Impact Assessment, the proceedings of the 1979 meeting of the UN Economic Commission for Europe (ECE), will aid anyone unfamiliar with the methodologies and techniques used for EIA. The ECE volume does, however, highlight the prevailing chaos whereby almost anything that quantifies, indicates or even mentions "impacts" is classified as an EIA. The conference lamented this state of affairs and one of its recommendations is for systematization. But there is a surprising lack of self-criticism in both books. Some of the scoring methods, for example, actually offend logic by placing cardinal numbers on ordinal rankings. Moreover, the call for systematization is negated by fairly regular references to the "flexibility" of EIA, as if this is a virtue rather than a euphemism for arbitrary procedures.

Both volumes would have greater claim to authority had they included contributions from economists. One example will suffice. In the USA the National Environmental Protection Act mandated EIA for public sector investments. A fairly Project Appraisal and Policy Review. Edited by Timothy O'Riordan and W. R. Derrick Sewell. Pp. 304. ISBN 0-471-27853-X. (Wiley: 1981.) \$36, £13. Environmental Impact Assessment. Proceedings of a Seminar of the United Nations Economic Commission for Europe. Pp.368. ISBN 0-08-024445-9. (Pergamon: 1981.) \$55, £23.

traditional cost-benefit analysis was to be included. Without it, one may observe, it is not clear how anyone is to decide whether the investment is worth while at all. Yet O'Riordan and Sewell speak of the overnarrow concern in cost-benefit analysis with "economic efficiency" while their coauthors speak of the deficiencies of planning procedures that cannot debate national "need", which is what economic efficiency is all about.

A further flaw is that the value system underlying EIA is not investigated in either book. Cost-benefit analysis attempts to reflect an aggregate of individuals' preferences. In EIA, though it is hardly acknowledged, it is the planners' preferences that count. Possibly the unease which a democrat should feel in this respect explains the emphasis given by some of the authors in the O'Riordan and Sewell volume to the need to link EIA to "public involvement", although one cannot be quite sure who the "public" are. An EIA that finally emerges as a matrix of impacts does at least provide information for local and central government, as the authors correctly emphasize. But that same matrix - consisting of incommensurable impacts, subjective assessments by planners and consultants, objective physical measures

which may or may not be disputed by experts — cannot then answer questions of social worth unless reduced to commensurable terms with the demands the development makes on resources, i.e. its money cost. Moreover, EIA is of limited value in assisting choice between alternatives unless the impacts in the matrix for one assessment are systematically greater or less than the impacts in the assessment of the alternative.

The most provocative essay in the O'Riordan and Sewell volume, by Nick Abel and Michael Stocking, questions whether EIA has any relevance to less developed countries. Their argument is basically that EIA enshrines Western values, thus providing inappropriate evaluations of development projects, for example by implicitly equating low economic output per capita with "backwardness". Their strictures are familiar but worthy of careful examination. Anyone who has worked in low per capita income countries will doubt if Westernized assessment procedures are quite so irrelevant, since the general aim of income expansion is wholly warranted. But there is an unquestionable need to place EIA and other appraisal techniques in the political context of the country in question.

To anyone looking for an "update" on the state of play in EIA these are useful volumes, *Project Appraisal and Policy Review* especially so. Sadly, however, neither book has come to terms with the underlying questions which any project appraisal needs to ask.

David Pearce is Professor of Political Economy at the University of Aberdeen.

#### Lives and work of the nervous doctors

W.F. Bynum

The Doctrine of the Nerves: Chapters in the History of Neurology. By John D. Spillane. Pp. 467. ISBN 0-19-261135-6. (Oxford University Press: 1981.) £25, \$50.

THE title of Dr Spillane's volume comes from Thomas Willis's (1621–1675) original definition of "neurologie" as the branch of medicine dealing with "the doctrine of the nerves". The word, of course, has since changed in meaning, and long before Willis the central nervous system and its associated nerves had been recognized as a

crucial custodian of our uniqueness: the recepticle of our sensations, originator of our movements, storehouse of our memories, the seat of our souls. Consequently, the study of the structure, functions and derangements of the nervous system has a rich history, as this elegantly written and beautifully illustrated book attests.

Unlike Caesar's Gaul, Dr Spillane's book is divided into four parts. He describes the classical foundations (Galen, Vesalius, Willis), the eighteenth-century obsession with the nervous system as the origin of most disease, the nineteenth-century establishment of experimental neuroscience and, finally, the flowering of clinical neurology in the late nineteenth century. The approach is primarily biographical and expository, which permits selectivity and places the value of the work on its individual sections rather than on any unifying synthesis. As the sub-title suggests, the book is a series of chapters rather than an integrated history.

This approach has its limitations and its strengths. Among the latter is the way it permits Spillane to bring his own neurological knowledge to bear on the ideas of his intellectual forebears. This is particularly true for the more recent neurologists such as G.B.A. Duchenne, W.R. Gowers and Silas Weir Mitchell, men whose names are invoked more often than their works are read. Spillane has also rehabilitated several men whose contributions are often forgotten: John Cooke (1756-1838) and John Russell Reynolds (1828-1896) fall into this category. Nearly 200 illustrations are neatly integrated into the narrative, and production standards are high.

On the other hand, such an approach can be self-indulgent and historically impoverishing. There is little social context for the individuals discussed, little consideration of the wider professional concerns involved in the emergence of neurology as a speciality, and little attempt to integrate Spillane's principal figures into mainstream medical history. Furthermore, the focus is too rigidly Anglo-American, with occasional excursions into France but little on the equally important German scene. M.H. Romberg gets some consideration, probably because his book was translated into English, but the earlier work of men such as K.F. Burdach, and the rich neurological and neuropsychiatric tradition created by Monakow, Westphal, Korsakoff, Benedikt, Wernicke and others are essentially neglected. It is also historically distracting to concentrate on organic diseases of the nervous system at the expense of "functional" disorders, hysteria for example, which so preoccupied physicians such as Weir Mitchell and Russell Reynolds. Aphasia and the neurological consequences of tertiary syphilis also get curiously brief attention.

It may seem ungenerous to carp at what Dr Spillane has failed to give us, when he has given us so much. For his book is a pleasure to read, and the copious use of quotation gives it the flavour of a sourcebook in the history of his discipline. It distils the secondary literature on many pioneers in neurology and the neurosciences. But it is decidedly chapters in, rather than a history of, neurology.

#### Ecology: much to be done in the North

Stanwyn G. Shetler

The Boreal Ecosystem. By James A. Larsen. Pp.500. ISBN 0-12-436880-8. (Academic: 1981.) \$45, £29.80.

ECOLOGICAL studies of the boreal forest region have proliferated in the past few decades, and synthesis of them is certainly overdue. Larsen's impressive and scholarly treatise is not all we might have hoped for, but it will be welcomed eagerly by all boreal biologists and allied students of the North.

The book proceeds from a consideration of the glacial-postglacial history of boreal vegetation to discuss soils, climate, plant communities, various processes, and the economic utilization and management of the boreal forest ecosystem. Although a substantial portion is devoted to presenting some of the author's own data from his 20 summers of fieldwork, overall the book is a review and analysis of other published works.

Despite the ambitious title, the work is less than a definitive treatise on the boreal forest biome. This is not a synthesis for animal ecologists - except for one interesting but general chapter on animal populations ("The Trophic Pyramid"), The Boreal Ecosystem deals with plants. Geographically, the author confines his treatment largely to North America, with the Canadian sector, where he has had the most experience, receiving the most detailed consideration. Eurasia, with twothirds of the world's boreal forest area, is compared briefly here and there, and the extensive Scandinavian and Russian boreal ecological literature is only lightly covered. The perfunctory paragraph on the Appalachian extension of the boreal forest, which long has intrigued American ecologists, is disappointing.

The study of boreal ecology, as ecology generally, often has been hindered by differences in method and terminology. Fortunately, Larsen wastes no time in equating "boreal forest" in the American sense with "taiga" in the Russian sense; thus he does not perpetuate the erroneous notion commonly encountered among North American botanists that taiga is forest-tundra. Probably no two ecologists use the term "muskeg" in precisely the same sense, and such pivotal terms as this, which the author uses throughout, should have been more explicitly defined at the outset.

Larsen, a modern quantitative plant ecologist, begins and ends with an expression of faith in modelling and systems analysis, and he never misses a chance to demonstrate the superiority of the continuum concept and method in analysing boreal forest communities. Continua do not reduce easily to definable systems, however. If he does anything with his wealth of data and description, he convinces us that there are many boreal forests

and environments — in short, many ecosystems, which form a baffling continuum from the tundra complexes in the north to the temperate complexes in the south. Though he drops generalizations here and there throughout the book, most never quite jell, and, while remaining optimistic about future breakthroughs, he is the first to concede that we have not begun to know how to elaborate a workable model or to put numbers into the equations.

We cannot hold him accountable for the untidy nature of ecological science, and we can applaud his quest for the grand synthesis. But Larsen never quite rises above description, in spite of his ecosystem point of view and emphasis on dynamics and process. Nonetheless, he does bring many fresh insights and promising quantitative methods to bear on some of the most fascinating but perplexing and intractable ecological riddles of the North: vegetation history, northern forest limit, nature of succession, permafrost, broad-scale vegetational uniformity masking great local variation, to name a few. His analyses of the forest boundary communities and environmental conditions (particularly the frontal air mass dynamics) and of the inadequacies of classic successional concepts are especially useful and enlightening.

Much of the book is too detailed and heavy-going for quick and easy comprehension, and Larsen's treatise comes off more as a compilation and review than as a challenging new synthesis. Nevertheless, as a compendium on the state of knowledge of the North American boreal forest and its ecotones to the north and south, this unique book is the best and most complete single volume available.

Stanwyn G. Shetler is a Curator of the Department of Botany at the Smithsonian Institution, Washington DC.

#### **Evolution writ small**

R.P. Ambler

Biochemical Evolution. Edited by H. Gutfreund. Pp.368. ISBN hbk 0-521-23549-9; ISBN pbk 0-521-28025-7. (Cambridge University Press: 1981.) Hbk £30, \$69.95; pbk £12.50, \$24.95.

THERE are two ways in which evolution can be studied at the biochemical level. One is by the traditional comparative approach, epitomized 40 years ago by Baldwin's An Introduction to Comparative Biochemistry (Cambridge University Press, 1940). The other is through molecular

W.F. Bynum is at the Wellcome Institute for the History of Medicine, London, and a co-editor of the Dictionary of the History of Science (Macmillan/Princeton University Press, 1981).

genetics, following changes in gene sequence, number and position, while speculating about the accompanying effects on gene products, and studying functional change through enzymology or population genetics.

These approaches are illustrated by the nine essays that make up the present volume. Pink's excellent chapters on the major histocompatibility antigens and on immunoglobulins illustrate the power of modern molecular genetics in systems where comparative information is very limited. Pink is well aware of the need to consider function in evolving macromolecules, although in the immunoglobulins relevant information is limited. Is it even necessary (p.249) to accept that V gene proliferation is under selective control? In contrast, Crecitelli's account of the vertebrate visual pigments has very little to do with evolution. Weeds and Wagner's chapter on muscle contraction considers Kretsinger's and Collins' speculations about the universality of the structure of the calcium-binding site in contractile and other proteins, but only touches on the question of the multiplicity of actin and myosin genes.

Rao, Hall and Cammack illustrate some of the weaknesses of the comparative approach in their chapter on the photosynthetic apparatus, in which the now conventional attempt is made to derive from a synthesis of the properties of present-day organisms a synoptic account of the history of metabolism on Earth. In contrast, Clarke, in an essay that has a wider scope than its title "Enzymes in Bacterial Populations" suggests, is wise and sceptical, for example in pointing out that early metabolic pathways, like organisms, may have become extinct. In her final sentence she emphasizes the speed with which microbial evolution is observed to occur, a paradox when contrasted with speculation that particular present-day bacteria are recognizably similar to pre-Cambrian organisms.

Peacocke contributes a useful chapter on methods of data handling for phylogenetic trees. The longest section in the book is from Schuster, who considers various aspects of prebiotic evolution. After a long explanation of hypercycles, he concludes that

many plausible models (for the origin of the genetic code and the formation of protocells) can be proposed, but it is very hard to decide between them or even to suggest experiments to prove or disprove them.

Overall, the book suffers from insufficient editorial guidance on chapter content and emphasis, and the introductory chapter by Gutfreund does little to link the rest of the book together or to point the way of future experiment or speculation.

R.P. Ambler is a Reader in Molecular Biology at Edinburgh University.

## All angles on contemporary cosmology

Bernard J.T. Jones

The Isotropic Universe. Monographs on Astronomical Subjects, 7. By D.J. Raine. Pp.253. ISBN 0-85274-370-X. (Adam Hilger, Bristol/Heyden, Philadelphia: 1981.) £19.50, \$49.

EDWIN Hubble made a number of discoveries of fundamental importance in establishing our picture of the Universe, foremost amongst which was the realization that the Universe is expanding. On the simplest level of interpretation this astonishing fact demanded an origin for the Universe at a finite time in our past — a "big bang". Of almost equal importance was the realization that the Universe looks the same at great distances in whatever direction one observes: this homogeneity and isotropy fitted in well with the simple cosmological models deduced by Friedman and Lemaître from Einstein's general theory of relativity. These observations led to one of the great controversies of modern science: the issue was whether the Universe really had a singular origin (the big bang theory), or whether matter was being continuously created so as to make up the loss due to the expansion (the steady-state theory). In 1965 the debate was resolved with the discovery of the cosmic microwave background radiation by Penzias and Wilson. This discovery established the idea of a hot, singular origin for the Universe, and subsequent measurements affirmed the isotropy of the Universe to better than one part in 104.

Cosmology thus became a physical rather than philosophical science, and with this change of emphasis came new questions. Why is the Universe so isotropic? Was it born that way, or did physical processes conspire to create the present isotropy? How did the present observed structure (galaxies and galaxy clusters) originate? What was the nature of the cosmic singularity?

These are the complex and often controversial issues which Derek Raine presents in this book without submerging the reader in a maze of equations and concepts from differential geometry. Of course, to go beyond a simple description of the issues requires more in the way of mathematical hardware, but that step is generally covered by adequate references to the more specialist literature. The discussions of "bang" and "whimper" singularities, and of rotating universes are particularly well done at this pedagogical level, though there are a few places where the going is quite hard (the Bianchi classification of homogeneous three spaces is perhaps the most challenging concept in the book).

Mach's principle, the "anthropic principle", the isotropy of the Universe and the arrow of time are all mentioned and put in context (but for some reason there is

no reference to Paul Davies' book *The Physics of Time Asymmetry*, published by Surrey University Press in 1974).

The Isotropic Universe is not confined to issues arising out of general relativity and the wish to explain space-time structure, though these are certainly the strongest and best-organized sections. The table of contents reads like a check-list of 95 topics every enthusiastic cosmologist should know something about, whatever his or her speciality. With a mere 250 pages in the book some topics get a rather brief treatment, though Raine succeeds in hardly ever lapsing into a "lecture-notes summary" style and maintains a consistent level of pedagogy. It is the pedagogical style that is, in my opinion, the book's strongest point. The discussion of the use of correlation functions and power spectra in studying the clustering of galaxies is a noteworthy example of this. As is often the case in teaching this subject, the mathematics becomes fairly complex for several pages. However, there are some good examples of the use of correlation functions and the two-dimensional power spectrum is treated via a projection of the sphere, thus eliminating the use of spherical harmonics.

So, who might benefit by reading this book? Although the author describes it as

power needs, and (5) educa-

an intermediate-level introduction, the unaided physics or mathematics graduate may have difficulty in many places owing to a lack of sufficiently diversified background knowledge. The professional mathematician or physicist should experience less trouble in this regard. However, as a teaching book for a graduate course, its style and organization are excellent. My major concern in this respect

lies in what I would regard as an aberrant choice of units (consistency with other noted texts in this field would have been most welcome) and a price that virtually excludes all but the most enthusiastic students.

Bernard Jones is at the Institute of Astronomy, Cambridge, and a Lecturer in the Department of Applied Mathematics and Theoretical Physics, University of Cambridge.

#### Molecular stickiness and its consequences

J.M. Creeth

Protein-Protein Interactions. Edited by C. Frieden and L.W. Nichol. Pp. 403. ISBN 0-471-04979-4. (Wiley: 1981.) £36.95, \$66.45.

THE past year has seen the publication of several quite advanced and thoughtprovoking texts in physical biochemistry -Spragg's The Physical Behaviour of Macromolecules with Biological Functions, Cantor and Schimmel's multivolume Biophysical Chemistry and Richards's more physically-inclined Introduction to Physical Properties of Large Molecules in Solution spring immediately to mind. Now we have Protein-Protein Interactions, and one should say immediately that it overlaps but little with the more general texts. It is a book which will satisfy the specialist, although the general biochemical reader might find it rather hard going in parts. Its main function will probably be to provide a point of take-off for those research workers facing a suspected problem in protein interaction, and in this capacity it should be excellent (although it must be noted that gel-forming protein systems are not included).

The range of topics covers both the essential ground work of elucidating protein structure and behaviour in solution two excellent chapters, these, with much of the mathematics compressed into an appendix - together with quite detailed surveys of the methods currently accepted as most useful. Winzor covers massmigration (including its many recent refinements), and there is an interesting account by Cox of the successful computer simulation of sedimentation velocity. Jeffrey's chapter on equilibrium methods deals mostly with sedimentation equilibrium, as one would expect from the vast amount of work done in the past decade. Although the methods may be used to analyse associations — even if complicated by heterogeneity, non-ideality and pressure-dependence of specific volumes - often, as is made plain, the unambiguous solution is singularly hard to obtain.

Hammes describes the extremely sensitive fluorescence methods and Frieden the more specialized techniques available

for interactions involving enzymes. Timasheff discusses the topical problems inherent in the self-assembly of rod- and tube-like polymers, and a final chapter by Nichol and Winzor deals with the profound questions of how biological control mechanisms can arise through interactions among macromolecules and between them and small molecules. A measure of the practical application of what may appear to be an abstract development is the inclusion here of a section on lymphocyte activation.

Whether physical biochemistry exists (or should do so) as a separate discipline has recently, and quite rightly, been questioned. Although many of us would prefer to minimize the distinctions, conscientious readers of this book will be left in no doubt as to the vitality of the discipline, and the readiness of its practitioners to tackle problems in the main stream of biology.

#### Potential reference

Paul Barnes

Intermolecular Forces: Their Origin and Determination. By G.C. Maitland, M. Rigby, E.B. Smith and W.A. Wakeham. Pp.616. ISBN 0-19-856611-X. (Clarendon/Oxford University Press: 1981.) £39.50, \$69.

THE four contributors to this work have clearly striven to produce a definitive reference text on the title-subject. The authors pay due respect to the classic treatise of J.O. Hirschfelder, C.F. Curtiss and R.B. Bird (*Molecular Theory of Gases and Liquids*; Wiley, 1954) but, rightly, also point out the need for a review of developments of the past quarter century.

First, they cover the historical perspective and basic statistical thermodynamic theory, then go on to discuss the relevant experimental techniques of molecular beam scattering, properties of gases and spectroscopy. Throughout this latter part the authors mostly keep to their main task of elucidating the intermolecular potential from the experimental data. The application to condensed phase (solid/liquid) potentials is reserved for Chapter 8, prior to the final summary (Chapter 9).

The format of the book is distinctly "reference style". There are the inevitable inhomogeneities in style and a degree of repetition, but the book is not intended to be read straight through; indeed, the authors are to be congratulated on making each section self-sufficient and, with this in mind, reading schemes are included. The extensive use of valuable appendices strengthens this approach, though even more use could have been made of them in places, for example for the lengthy quantum-mechanical derivations and scattering theory in Chapter 4 on molecular collisions.

The general approach to the subject is one of caution and commendable rigour. The authors continually try to point out the lessons to be learnt from the past (for example, the excessive use of oversimplistic potentials, neglect of pairwise non-additivity, fitting of potentials to inaccurate experimental data) and to define clearly the status of current research on potentials. The deliberate omission of hydrogen-bonding and ionic interactions is a key factor — this allows them to maintain their rigour throughout the book, though in doing so it could rob them of a larger "potential" readership.

This book will be well suited for those wishing to gain a good grounding in the use and elucidation of intermolecular potentials for the simpler systems, and also for those who may need to extract just part of that wealth of detail. Among such people will be computer simulation workers who, incidentally, may feel that the debt of the subject to computer simulation (or numerical quantummechanical calculations) has not been fully acknowledged; only three pages are directly devoted to computer simulation (in Chapter 8 on condensed phases), yet it can be argued that the development of computing is a primary reason for the advances made since the work of Hirschfelder, Curtiss and Bird, and also represents one direction where many further advances are to be expected. For all this, Chapters 7,8 and 9 (on spectroscopic measurements, condensed phases, and our present understanding of intermolecular forces) are particularly enjoyable and are recommended for inclusion in a "first read".

Despite the somewhat cautious approach and the limited range of bonding species discussed, it is to be hoped that many readers will sample this worthy book.

Paul Barnes is a Lecturer in the Department of Crystallography at Birkbeck College, University of London.

#### **Biochemicals**

# The increasing cost of consumables

THE Medical Research Council of the United Kingdom, in its annual report for 1980-81 published two weeks ago, drew attention to the consequences for its support of research projects of the increasing costs of consumables. In reality, the council appears to have relatively little to complain of, for it was apparently able to persuade the Advisory Board for the Research Councils (which advises the Department of Education and Science on the division of research funds between the research councils) that some allowance should be made for the way in which the costs of consumables have increased more quickly than retail price indices in the past few years. Understandably, however, there are fears for the future, and not merely in Britain. When all grant-making agencies' budgets are stagnant (or falling), is there a danger that research programmes will be cramped for want of the funds with which to buy consumables?

The simple answer is yes; in the future as in the past, the lack of petty cash (or the authority to sign order forms) will prevent some investigators from doing what they wish. The more important question is whether the investigators that matter, those likely to break new ground, will be hampered in their work. There, most probably, the answer is no. There are good reasons why the fields in which the cost of consumables is most onerous are also novel fields, which most grant-making agencies are likely to have backed with some enthusiam and thus generosity.

#### Recombinant DNA

Thus it is that recombinant DNA research has become, a little to its practitioners' surprise, one of the fields in which the cost of consumables has become most conspicuous. One unit working in the field now reckons to spend roughly a third of its total costs (salaries, but not heat, light and general overheads) on consumables. Radioactively-labelled compounds and restriction enzymes are the chief cost, with fetal calf serum (at about £100 a litre) a steady drain on the budget because the laboratory is also involved with culturing animal cells. The unit reckons that it would be spending even more on consumables if it bought in, as it might, regular supplies of dinucleotides and perhaps even customsynthesized oligonucleotides - a milligramme of a 14-unit oligonucleotide synthesized to order will typically cost \$4,000.

Part of the explanation of these high costs is nevertheless readily understood—and widely accepted by potential customers. In this field as in others in the past, the materials that laboratories buy from suppliers include many which would,

until recently, have been made in the laboratory by the research people themselves. Synthetic oligonucleotides, used for example as probes for particular DNA structures within genes or as building blocks for the synthesis of larger pieces of genetic material, are a good illustration. Indeed, many laboratories prefer, at least for the time being, to make such materials for themselves on the grounds that, in that way, they can be sure that they have synthesized the intended product. But the skilled time required can be substantial.

#### Why buy?

Thus the alternative of buying in from a commercial company is in essence a means of augmenting a laboratory's manpower. Moreover, even at the prices at which materials are supplied, buying-in may be entirely economic when account is taken not merely of the salaries of those who would be occupied with in-house manufacture but of the way in which senior people would be diverted from more creative work by the need to synthesize, or supervise the synthesis of, straightforward chemicals. The old proverb "Penny wise, pound foolish" applies, even though all grant-making bodies may not yet agree.

These circumstances are neither novel nor unfamiliar. Most types of scientific instruments, for example, have usually begun their existence as custom-built machines developed by a single investigator. Even when commercial machines appear on the market, some investigators prefer to make their own versions, partly for the sake of extra sensitivity or flexibility. The point at which a laboratory decides to rely on commercial instruments must necessarily vary from one place to another. One telling consideration is usually the question of when academic laboratories can no longer match the engineering quality of commercial instruments. But there are frequent examples, perhaps more common in the physical sciences, where commercial versions of valuable hand-built equipment never appear, with the result that investigators must reconcile themselves to remaining partly instrument engineers.

One of the reasons for some of the confusion in the commercial supply of chemicals used in recombinant DNA research is linked with the rapid growth of interest in the field at laboratories not previously involved. At the same time, the widespread sense that the recombinant DNA field offers opportunities for entrepreneurs seems to have stimulated the formation of a number of small commercial organizations offering to supply a comprehensive list of materials in some narrow field — dinucleotides and

oligonucleotides for example. As things are, one man, a few technicians and an automatic nucleotide coupler may constitute a business.

Classically, the economists would predict that these circumstances would first stimulate competition, driving prices down. But it is by no means clear whether the market is sufficiently price-sensitive to have this effect. Another possibility is that the newer smaller companies will find it convenient to operate under the wings of larger and well-established concerns more skilled at distribution but anxious (as always) to supply as wide a range of biochemical materials as possible.

Signs of change are already under way in the market for monoclonal antibodies, the most immediate potential source of income for the host of genetic engineering companies set up in the past few years. Eventually, no doubt, some monoclonal antibodies will turn out to have a substantial market, perhaps in the purification of interferon or other proteins with a large potential usefulness in the pharmaceutical industry.

No doubt the market for these products will be determined internationally by means of competition between the suppliers. More specialized antibodies, used only in research, are likely always to be more highly priced. Their suppliers will, however, always be well aware that users in research laboratories can make their own - and will not be prevented from doing so by whatever patent protection applies to the commercial use of the materials. Moreover, many small suppliers must be acutely aware that their costs do not rise linearly with the quantities of these materials they can sell. Competition and sales apparently account for the quite sharp reduction of the prices of monoclonal antibodies in the past few months.

The prospect, then, is that the present high cost of the specialized biochemicals that recombinant DNA research has foisted on itself may well be abated as the years or even months go by. Their places at the top of the lists of expensive biochemicals will no doubt be taken by other materials whose importance is not yet apparent — and which may not yet exist.

#### No saving

Whatever happens to the cost of individual biochemicals, however, there seems no doubt that the cost of consumables in biochemically inclined laboratories will continue to increase. Several laboratory managers report that in the past few years they have been spending increasing amounts on restriction enzymes as increasing numbers of research groups take an

interest in recombinant DNA research. In real terms, the unit costs of these materials seem not to have risen in the past year or so, although they appear also not to have fallen as increased usage might have made possible.

Other natural products are a less predictable burden for laboratory accountants. The recent vagaries of the market in fetal calf serum seem to have been a particular source of trouble and for a variety of obscure reasons.

Fetal calf serum is an essential ingredient of much tissue culture work, but for reasons that remain obscure. The material itself is a by-product of abattoirs, and its supply thus depends to some extent on farmers' willingness to see their cows slaughtered while carrying calves, which is in turn a function of their estimate of the future trend of agricultural prices.

Twelve months or so ago, supplies of fetal calf serum were exceedingly hard to come by, and also expensive — at the peak of the market, the price exceeded £150 a litre. The explanation seems to have been that a fluctuation in the supply of fetal calves coincided with the decision of several commercial companies to produce substantial quantities of interferon from cell lines cultured in the presence of fetal calf serum.

#### Limited choice

At the height of the shortage, investigators were perhaps less distressed by the price of fetal calf serum than by suppliers' suspension of their previous practice of supplying samples from several batches of serum so as to allow the choice of a batch found suitable for intended tissue cultures. Although this practice has now been restored, and many laboratories have also found ways of economizing in their physical use of fetal serum - either by using less of it or by substituting other materials (such as newborn or even adult bovine serum) - anxiety persists that demand for material may eventually permanently overtake the natural supply. The question naturally arises whether the genetic manipulators should not now set out to help their colleagues in tissue culture laboratories by identifying the essential ingredients of fetal calf serum and, if need be, making them artificially.

The third important area of spending on consumables that seems to laboratory managers a heavier burden now than previously is the purchase of radiochemicals. As with restriction enzymes, the underlying difficulty is that laboratories are now using more of these inherently expensive materials, and in a greater variety of formulations.

The cost of radiochemicals is to a large extent determined by the salaries of those who make them. And even though there has been in the past few years a substantial growth of the demand for certain materials, small batch-production is still necessary for most radiochemicals.

Interest in recombinant DNA techniques has for example enormously stimulated the consumption of nucleotides labelled with <sup>32</sup>P.But with its short half-life of 14 days, and the usual problems of chemical degradation caused by radioactive decay, it is still necessary to supply batches of material against firm advance orders.

The manufacturers are shy of saying how much new business has been stimulated by recombinant DNA research, although some estimate that the demand for some of the more widely used radiochemicals is doubling every few months. Both the principal suppliers (Amersham International and New England Nuclear) are seeking to meet the needs of their new customers by making up radiochemicals in more convenient formulations — labelled nucleotides, for example, may be supplied in aqueous solution (thus avoiding one tedious preliminary step).

The trend towards the supply of radiochemicals with greater specific activity has also continued. Ultimately, radiochemicals of all kinds are used in some form of assay. the sensitivity of which depends inherently on the fraction of atoms at labelled site which are radioactive. Some of the <sup>32</sup>P nucleotides now available have a specific activity that is more than half the theoretical maximum, implying that more than half of the nominated phosphorus atoms consist of <sup>32</sup>P. Superficially, these materials are not disproportionately more expensive than others with less specific activity. To investigators, enhanced sensitivity and the opportunity to use smaller quantities of material are advantages that probably always outweigh the extra cost.

Even so, quite small laboratories using substantial amounts of radiochemicals consider it well worthwhile to make special deals with the suppliers. The usual arrangement is that a laboratory will undertake to buy during a year radiochemicals of more than some specified value, winning a discount on catalogue prices in return.

Although laboratories which are parties to such special arrangements are usually fiercely proud of having wrung a tough bargain from the suppliers, the arrangements are probably mutually beneficial. In the radiochemicals business, distribution costs are inevitably high, with the result that there must be substantial economies to be won from the repeated use of some well-known distribution route. But there are obvious limits on the extent to which the pooling of business from several laboratories can be used to negotiate even larger discounts from the suppliers of radiochemicals - people need to order their supplies individually and cannot risk the delays, real or imagined, that some central purchasing agency would imply.

So how much does it cost to support with consumables a scientist at the bench? This question, beloved of grant administrators, is now virtually unanswerable. One recombinant DNA laboratory in Britain

estimates that the annual cost of consumables for its particular programme now exceeds £3,500 a year for each working scientist (graduate students and technical assistants included). A similar laboratory in the United States puts the annual cost at "getting on for \$10,000". There is some evidence that larger costs may be incurred in industrial research laboratories working in these expensive fields, no doubt because those working in a commercial setting are more likely to be encouraged to augment their own labour by means of materials bought in from outside.

The relatively high cost of consumables in some fields, however, appears not yet to have much affected the rule of thumb that large laboratories with a diversified programme of research tend to spend about 10 per cent of their total budget (heat and light included) on consumables. Electron microscopists, or those working on X-ray diffraction analysis, can after all get by well enough with photographic film and perhaps a little liquid nitrogen. There is no general rule that capital equipment obviates the need for expensive consumables, as those working with radioimmunoassay know to their cost. Yet it does appear that in any large and diversified laboratory, there will be some investigators whose spending on consumables is for practical purposes negligible.

Many investigators complain, however, that the degree to which the cost of consumables must vary widely from one laboratory to another, according to the nature of the research programme, has not yet been fully appreciated by the grant-making agencies. Moreover, they argue that in the writing of research grant proposals, it is virtually impossible to calculate with any semblance of accuracy the quantities of expensive materials that will be consumed over a period of, say, three years ahead. The agencies, however, have their own internal needs of tidy accounting, although those which are the chief sources of support for research programmes in molecular biology appear to have devised effective ways of functioning flexibly.

#### Supplement to grants

The ideal, from many points of view, would be that grant-making agencies should agree that grant recipients in the fields in which consumable costs are highest should reconcile themselves to regular supplementary requests for funds, perhaps at intervals of six months or so during the tenure of a research grant. At least where university researchers are concerned, there is now little chance that costs can be met from university budgets.

Small research groups such as these are also less able to insulate themselves from the cost of consumables than research laboratories and institutes with their own integrated administration. In such laboratories, administrators seem to be increasingly self-conscious about the costs of consumables, and more eager than ever

to devise ways of making research groups more aware of the high costs that may be involved in their work.

Bulk purchasing seems to be one of the most commonly used devices for keeping expenditure within bounds, and appears to be most effective when applied to what may be called "dry goods" — rubber gloves and small but frequently used items of plastic ware, the cost of which seems to have increased substantially in the past few years. (The common explanation, that plastic materials are oil-based, and that their increased cost reflects the increased international cost of oil, is not all that convincing, for the quantities of hydrocarbon involved are only very small.)

#### **Bulk contracts**

In this spirit, many laboratories appear to have been able to negotiate contracts for the supply of small disposable but widely used items of equipment which offer substantial discounts, sometimes more than 30 per cent, from catalogue prices. Under these arrangements, laboratories may place an order covering twelve months ahead, drawing off supplies as needed from the manufacturer (and thus avoiding the cost of storage in the laboratory and the risk that materials will be lost, damaged or used profligately). Larger laboratories are sometimes able to buy widely used consumable items by asking suppliers to tender for them.

Despite the financial advantages there may be from such arrangements, however, research administrators seem well aware of the limitations of bulk supply. Requiring that orders for standard items of equipment should be channelled through a central office rather than directly from a laboratory to the supplier can cause delay. Moreover, the problems of identifying in advance a laboratory's need of common items of disposable equipment are in themselves formidable. The results may often be uncertain.

There are also limits to the extent to which individual investigators can be persuaded to order biochemicals from some standard supplier, able and willing to supply in bulk. People are rightly unwilling to change from one source of supply to another in the middle of a series of experiments. Equally, there may be frequent occasions when it is necessary to follow some other investigator's recipe for carrying out some experimental procedure.

In the circumstances, laboratory administrators appear to accept, the best hope for economy is that investigators themselves will be conscious of the cost of the materials they propose to use. Those whose research is supported by identifiable grants are encouraged to examine the bills their work generates, signing the invoices personally when this is appropriate. The risk that over-spending may make it necessary to look for extra funds from departmental or institute resources is usually a powerful restraint. The

competing interests of colleagues are more effective spurs to economy than pleas from accountants and managers.

In many laboratories, invoices are centrally scrutinized as a matter of routine, but usually with discretion and tact. Given the wide currency of the impression that the costs of consumable materials have suddenly become onerous, it is surprising that there are apparently few complaints of bumbledom and over-zealous interference.

One of the most effective ways of engendering a sense of economy among investigators, however, is to arrange that they are notionally required to pay even for commodities and services that would normally be provided free of charge. Such a system is operated at the Institute of Cancer Research in London, and covers the provision of services as different as electron microscopy, photography and the supply of laboratory animals.

For practical purposes, close on a fifth of the total cost of the institute's operation is charged out internally in this way. For simplicity, the cost of various units of service is counted in simple standard units — the cost of producing one electron micrograph is reckoned to be very much like that of another. The products of the animal house are reckoned in "mouse units" — the cost of a single mouse. One rat supplied is reckoned the equal of two mouse units, and so on.

#### Self service

Broadly speaking, each of the service departments is required more or less to break even in the course of a year, covering its own salary and equipment costs but not counting general overheads (heat and light) or the cost of management. The result is that the internal services have on the face of things a cost advantage over external suppliers, at least if they operate on a reasonably economical scale. One result has apparently been to persuade investigators to think twice before signing maintenance agreements for equipment which can technically be serviced by the institute's own electronics department.

Both the managers and the users of this system speak well of its effects, psychological though they may be. Investigators apparently welcome the chance to spend their notional money with the service departments, thus avoiding the need to wheedle and cajole people into compliance with their needs.

Such systems for sharing out the internal costs in laboratories have obvious snags, not the least of which is that the supposed arms-length relationship between the service departments and their customers must in practice be modified by a regular exchange of information between the two sides so that the suppliers can make a reasonable attempt to match their supply with the likely demand. It would serve very little purpose if an institute's animal house became a large and efficient producer of laboratory mice if the chief need had

switched from mice to rats.

There is also the obvious danger that such laboratories might become so well used to the convenience of this service arrangement that they cease to be vigilant in calculating their real costs. In the long run, the only effective safeguard is that investigators should be free to buy from outside their own laboratory if the prices there are potentially more attractive. Perhaps the most serious difficulty is that internal service departments are likely to enjoy comparatively low prestige, and thus less ready access to the funds necessary if they are to be properly equipped so as to remain efficient.

Obviously the scope for such arrangements is confined to laboratories with a certain amount of freedom to determine how resources are divided internally. The practice closely follows that in many industrial research and development laboratories, where the cost of supplies drawn from central stores will commonly be used as a management tool for assessing the cost-effectiveness of a research programme.

It is understandable enough that laboratory managers — or at least the more effective among them — should be more proud of the devices by means of which they have encouraged economy among investigators than they are distressed by the cost of consumables. At the same time, it does appear that the area of research in which the cost of consumables has recently sharply increased is probably sufficiently narrow not to have affected the general cost of research.

Objective figures are hard to come by. A document published twice a year in the United Kingdom by the Committee of Vice-Chancellors and Principals, and which purports to provide a breakdown of the general university costs, shows that the cost of a broad category which includes laboratory consumables has, in the past few years, increased at a pace almost identical with that of inflation. But this index, known as the "Brown index" after its original compiler, is probably too crude a measure to reveal the consequences of the increased cost of consumables in those fields in which the pattern of people's research has changed.

One feature of the recently discovered high cost of consumables in some hitherto shoestring fields such as molecular biology is, however, plain. While many grantmaking agencies may have learned to adapt to these high costs, in present circumstances there is very little hope that university laboratories will be able to meet them out of their own departmental allowances. Moreover, the provisions now made for graduate education fall far below the costs likely to be involved. So while there is no direct evidence that the work of active and well-supported groups is at present being restricted, there is a danger that entry into the field may be hampered by the high cost.

## DRRESPONI

#### Continued from page 302

results should the crops be attacked by more than one pest. Chemical pesticides are still the main component of most methods of integrated control and several progressive companies have now developed insecticides (chlorvinphos) that are particularly suitable for this purpose.

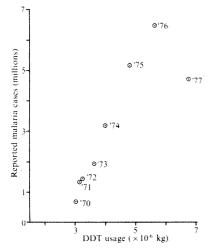

Integrated pest management is now accepted and promoted by WHO and FAO wherever scientific agriculture and progressive health programmes exist. No doubt wider use of this approach is desirable but this depends largely on the availability of well trained specialists and on the understanding by farmers of the need for restraint in the use of chemicals. In this respect the paper by Chapin and Wasserstrom is of some value, although its sensational presentation (with sub-titles such as "Deadly link") undermines the credibility of the authors involved.

Sir — It is generally agreed among malariologists that agricultural insecticides have made a contribution to selection for insecticide resistance in mosquitoes and that such resistance has made a contribution to the resurgence of malaria in Central America and South Asia. It is also generally agreed that one should be very careful before inferring a causal relationship from the discovery of a correlation between two sets of measurements.

No such care was exercised by Chapin and Wasserstrom (Nature 17 September p.181-185). They infer that in El Salvador

"each kilo of insecticide added to the environment will generate 105 new cases of malaria". Taken literally and from their own data this would imply 168 million cases of the disease in a country with a population of 4.3

Chapin and Wasserstrom present three figures with apparently calculated points and

lines but no actual data points. Each graph has a correlation coefficient marked on it of 0.96 or 0.99, but, especially in the case of the curvilinear relationships, the reader has no means of assessing how these coefficients were calculated. Their Fig. 1 is entitled "Effect of DDT on rice production in India, 1970-77" as if the correlation between these two parameters were a simple causal one. In fact, however, it is well known that other independent factors, notably the introduction of high yielding varieties, have both boosted rice yield and allowed and/or required more insecticide usage.

The basis of Chapin and Wasserstrom's curves (Figs 2 and 3) purporting to relate malaria incidence in India during 1969-77 to DDT usage and rice production, is unclear. In the figure (see below) I have plotted the data on malaria incidence issued by the Indian National Malaria Eradication Programme (NMEP) against the data shown by Chapin and Wasserstrom (Fig.4) for DDT usage. Certainly both quantities tended to rise over those years but so did other probably relevant factors such as irrigation. My graph shows a much less startling relationship than Chapin and Wasserstrom's because, according to the NMEP data, the minimum number of cases was higher, the maximum was lower and the malaria resurgence peaked in 1976 (and is reported to have continued to fall in subsequent years). No doubt the NMEP figures greatly under-report the true incidence of the disease, but there seems no reason to suppose that this under-reporting was greater

in the later years than in the earlier: Chanin and Wasserstrom give no information about any "correction factors" which they may have applied to the available data. I conclude that Chapin and Wasserstrom's graphs give a grossly misleading impression that there is a simple causal relationship between agricultural insecticides and malaria.

That the relationship is actually more complex is indicated by the following facts:

- (1) Spraying of cotton crops has the, at least short term, beneficial side effect of suppressing mosquito populations.
- (2) The large tonnage of insecticides used in anti-malaria spraying has certainly contributed to the selection for insecticide resistance in mosquitoes, as shown by the fact that withdrawal of this spraying has been found to lead to a levelling out or decline in the frequency of resistance genes.
- (3) In the Gezira area of intensive agriculture in Sudan, resistance in Anopheles arabiensis is to malathion which is used in anti-malaria spraying and not to the other organophosphates used for spraying the cotton crop.
- (4) Sri Lanka has very wisely banned the use of DDT and malathion in agriculture and reserved them for the anti-malaria campaign but has still had a hard struggle to contain and reverse its resurgent malaria problem.

C.F. CURTIS

Ross Institute, London School of Hygiene and Tropical Medicine, London, UK

#### A reply —

Sir - We are sorry that Professor Bruce-Chwatt disagrees so radically with our interpretation of the facts surrounding malaria resurgence in India. In our own defence, however, we would suggest that the military conflict with Pakistan, the sharp fall in the flow of American aid, the temporary food shortages that took place there between 1973 and 1975, etc., do not explain the abundant entomological reports of Anopheles resistance which we cited in our article - even from such prosperous agricultural regions as Maharashtra and Guiarat. These reports. together with official accounts of the deliberations within WHO and FAO. constitute the major source of evidence upon which we have based our analysis

Finally, like Professor Bruce-Chwatt, we appreciate the difficulties of implementing effective systems of integrated pest management in tropical areas. It was during the successful development of one such system in southern Mexico that the idea of writing this article first occurred to us.

In reply to Dr Curtis, it is unfortunate that in the process of reproducing our illustrations, many of the data points have become difficult to discern. Disregarding for the moment the 1979 figure on malaria incidence in India. however, Dr Curtis's information suggests an even higher correlation between DDT usage and the spread of disease than we have calculated. As for the question of decreased transmission, it may well be true that malaria in India peaked in 1976, but the 1977 figure he cites has been questioned by numerous specialists and in any case does not contradict

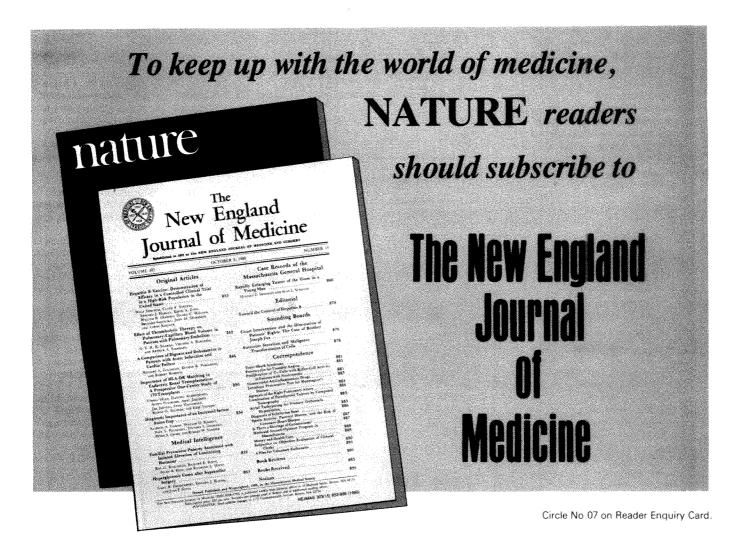

our argument about pesticide abuse.

As for the four points raised in his letter, we offer the following response:

- (1) It is precisely the short-term beneficial effect of insecticides that encourages cotton growers and public health officials to apply them. What we have argued, however, is that the disadvantages of insect resistance soon come to outweigh these rather ephemeral benefits.
- (2) It is difficult to separate the effects of insecticides used for malaria control and those used in agriculture. What is clear, however, is that the decline in resistance after anti-malaria programmes are discontinued is a limited and unfortunately rare phenomenon.
- (3) Although it may be true that Anopheles mosquitoes in Sudan are not resistant to the organophosphates used on cotton, most countries have not been so lucky. How does Dr Curtis explain the almost complete and apparently irreversible resistance among malaria vectors in India, South-East Asia and Central America?
- (4) As the case of Sri Lanka indicates, restricting the use of a particular chemical does not guarantee that mosquitoes will remain susceptible to it: application of related (and even unrelated) compounds is often sufficient to stimulate resistance. Moreover, if initial success in combating malaria leads to the reduction of screening and treatment procedures (as commonly occurs), epidemic resurgence will indeed be exceedingly difficult to control.

ROBERT WASSERSTROM GEORGANNE CHAPIN

Columbia University. New York, New York, USA

The New England Journal of Medicine presents to its readers original articles of clinical-scientific material and interpretive reviews in the major disciplines of medicine. In this highly competitive field less than 10% of the manuscripts submitted are accepted for publication because of the rigid editorial policy that articles must reveal something new or be an extension of existing knowledge.

Every week, more than 200,000 subscribers keep up to date with the world of medicine through The New England Journal of Medicine. To join them, just fill in and mail the coupon today.

#### $\mathsf{BRL}$ ® PRODUCT REVIEW

Bethesda Research Laboratories, Inc. P.O. Box 6009•Gaithersburg, MD 20877
BRL GmbH Offenbacher Strasse 113 6078 Neu Isenburg•West Germany
BRL Bethesda Research Laboratories (UK) Ltd.P.O. Box 145•Science ParkCambridge• England CB4 4BE

#### BRL® Ultra Pure Reagents

Bethesda Research Laboratories' expanding line of Ultra Pure and Specialty Reagents are examined analytically as well as functionally to assure you high quality reagents which will yield consistently accurate and reproducible experimental data. BRL offers a complete line of gel electrophoresis reagents, enzyme grade reagents and several unique specialty reagents which are used in molecular biology and protein biochemistry applications.

Gel Electrophoresis Reagents

#### Acrylamide

BRL® Gel Electrophoresis Grade Acrylamide is 3-fold recrystallized to ensure a highly purified product free of contaminants. The content of acrylic acid in BRL® acrylamide is <0.001% at time of manufacture.

Typical Lot Analysis:				
Assay				99.9%
M.W				
Acrylic Acid content				
A252 of a 7mM solution				
pH (10% solution)				$6.5\pm0.5$

#### N,N'- Methylenebisacrylamide

BRL® Gel Electrophoresis Grade N,N'-Methylenebisacrylamide is available as a white recrystallized solid. Acrylic acid content is less than 0.1% and heavy metal content is less than 1.5 ppm to ensure compatibility with nucleic acid and protein work.

Typical Lot Analysis:
Assay99.9%
pH (10% solution)>5.5
A290 of a 1% solution<0.2
Acrylic Acid content<0.1%
Heavy Metals (as Pb) <1.5 ppm

#### Agarose

BRL® Gel Electrophoresis Grade Agarose is highly purified and tested for use in nucleic acid separations. BRL® Agarose is routinely used in our laboratories to visualize DNA fragmentation patterns generated by restriction endonucleases

Typical Lot Analysis:	
Gelling temperature at 1% conc	36-40°C
Moisture	
Sulfate	< 0.35%
Ash	<0.75%
Electroendosmosis (-m <sub>r</sub> )	0.10-0.15

Other gel electrophoresis products include: Sodium Dodecyl Sulfate, Glycine, TEMED, Ammonium Persulfate, Coomassie Brilliant Blue R-250, and Low Melting Point Agarose. All have been specifically prepared and tested for use in gel electrophoresis.

#### Ultra Pure Enzyme Grade Reagents

#### Phenol, Crystalline

BRL® Phenol is redistilled and highly purified for the most critical nucleic acid extractions and chromatographic separations. A white crystal in appearance, redistilled phenol is free from interfering levels of heavy metals and inhibitors including H<sub>3</sub>PO<sub>2</sub>. Phenol should be stored at -20°C and is stable for several months. The reagent is packaged in a convenient amber bottle with space provided for the addition of solvent.

#### Cesium Chloride

BRL® Cesium Chloride is specifically designed for use in density gradient determinations used routinely in molecular biology and biochemistry. All samples have been checked to ensure that the  $A_{260}$  of a 50% (w/v) solution is zero.

This property becomes important when high purity is required or when relatively less defined systems are fractionated on gradients. This grade of Cesium Chloride can fulfill the needs of most researchers working with virus banding, nucleic acid (DNA, RNA) purification and in studies dealing with nucleoproteins.

Typical Lot Analysis:	
Purity	>99.999%
O.D. of a 50% (w/v) solution at	
260 and 280 nm	< 0.02

BRL also offers high purity Tris, Tris HCl, Urea, Guanidine HCl and Sucrose. All have been prepared to exacting specifications to ensure high purity levels.

#### **Specialty Reagents**

#### **Bovine Serum Albumin**

BRL® Bovine Serum Albumin is acetylated to inactivate contaminating nucleses and proteases.

Each lot of BRL® Bovine Serum Albumin is assayed for exonuclease and phosphatase activity by incubation with 3'- and 5'-end labeled [\$^{32}P\$] DNA. Absence of contaminating endonuclease and ribonuclease is determined by incubation with SV40 Component 1 DNA and ribosomal RNA, and their subsequent analyses by electrophoresis in agarose and denaturing urea gels, respectively. Protease activity is similarly checked by electrophoresis on a 10% SDS-polyacrylamide gel, using ovalbumin and  $\alpha$ -phosphorylase as substrates.

#### Vanadyl Ribonucleoside Complex

Vanadyl Ribonucleoside Complex(VRC) is an effective ribonuclease inhibitor used during cell fractionation and preparation of RNA. Buffers prepared 10 mM in VRC create optimal conditions for ribonuclease inhibition. VRC is supplied as an aqueous solution at a concentration of 200 mM.

#### Isopropylthio-β-D-galactoside

#### 5-Bromo-4-chloro-3-indolylβ-D-galactoside

Circle No. 11 on the Reader Inquiry Card.

# PRODUCT REVIEW

#### Linamarin determination

Now manufactured by BDH Chemicals, Linamarase is a purified enzyme preparation used for determination of linamarin. It has previously proved difficult to distinguish quantitatively between linamarin and free cyanide present in cassava but Linamarase removes this difficulty.

Circle No. 101 on Reader Enquiry Card.

#### Enzymatic diagnostic test

An addition to the ECS range of enzymatic diagnostic test systems is now available from Bio-Rad Laboratories. The ECS uric acid test system depends on a two-stage enzymatic reaction. In the first stage, uric acid is oxidized to allantoin and H<sub>2</sub>O<sub>2</sub>. During the second reaction, the peroxidasemediated oxidative coupling of phenolic dve compounds with 4-aminophenazone results in the formation of a quinoneimine dve, the concentration of which is proportional to the amount of peroxide present and which can be determined by absorbance measurements at 520 mm. Uric acid estimations are valuable indicators in diagnosis of gout and renal dysfunction. Circle No. 102 on Reader Enquiry Card.

#### Hexokinase

SINGLE vial hexokinase is highly specific for glucose, the enzymatic procedure being based on its catalytic action on glucose and ATP, yielding glucose-6-phosphate. Uric acid, ascorbic acid and other substances which interfere with tests dependent on glucose oxidase, do not interfere with this product. The reagent is supplied by Alpkem and can be used with any instrument capable of accurate absorbance readings at 334, 340 or 366 nm. It is highly water soluble and has a stable refrigerated shelf life of up to 18 months.

Circle No. 103 on Reader Enquiry Card.

#### Anti-human fibronectin

AVAILABLE in aliquots of 2 and 10 ml, rabbit anti-human fibronectin antibody is offered by Accurate Chemical & Scientific Corporation.

Circle No. 104 on Reader Enquiry Card.

#### Diagnostic reagents

PREPARED from the Cowan 1 strain of Staphylococcus aureus, the new Staphylococcal Protein A Insoluble reagent from Oxoid is available as a suspension of the heat-killed, formaldehyde-treated cells at a concentration of 25 g dry wt (100 g wet wt) per 1 of buffer. The binding capacity of the reagent for human IgG is 1.5–1.9 mg per ml of suspension. This product is one of the new Oxoid diagnostic reagents range. Circle No. 105 on Reader Enquiry Card.

#### **Scintillation solutions**

LIQUID scintillation counting is described in a brochure from National Diagnostics, which gives details of counting solutions, such as Hydrofluor, intended for use undiluted in aqueous samples. Also included are Dimiscint, which inhibits chemiluminescence, and Autofluor, an autoradiographic image enhancer.

Circle No. 106 on Reader Enquiry Card.

#### **DNA** sequencing vectors

NEWLY available from New England Biolabs as RFI DNA are M13 lac cloning vectors M13mp8 and M13mp9. In addition to the EcoRI, BamHI, AccI, Sall, HincII and PstI sites of M13mp7, these vectors contain Xmal, Smal and HindIII sites. Each of these cloning sites occurs only once within the gene encoding  $\beta$ -galactosidase. Therefore, not only can cloned fragments be selected on the basis of colour on an indicator plate, but insertion of a fragment with two different termini is possible ('forced cloning'). The cloning sites in M13mp8 are aligned in the opposite orientation from those in M13mp9, allowing the orientation of the cloned fragment to be chosen by selecting the appropriate vector.

Circle No. 107 on Reader Enquiry Card.

#### Proteolytic enzyme assay

A PAPER from Varian, 'Assay of proteolytic enzymes using the Varian DMS 90 spectrophotometer, thrombin assay using oligopeptide p-nitroanilide substrates', briefly describes the presence in all living organisms of proteolytic enzymes which function both in metabolism and in complex reactions that modulate the activity of other enzymes.

Circle No. 108 on Reader Enquiry Card.

PRODUCT REVIEW — The product review this week features biochemicals. The notes on these pages are prepared from information provided by the manufacturers. For more details use the reader enquiry card bound inside the journal. The next product review (14 January 1982) deals with water purification and analysis.

#### Bovine serum albumin

ENZYME stabilizer grade bovine serum albumin (BSA; ERT-701) is available from Enzo Biochem. It is free of nucleic acid and protein degrading activities as determined with the appropriate substrates. This product will remain a monomer even after prolonged storage. Enzyme stabilizer grade BSA is supplied in 10-mg quantities at a concentration of 20 mg ml<sup>-1</sup>.

Circle No. 109 on Reader Enquiry Card.

#### **Endotoxin detection**

ENDOTOXINS in water, sterile materials and ingredients for pharmaceutical products can be detected using a new test system from Laboratory Impex. This system detects the presence of Gram-negative endotoxins, is more sensitive than the USP rabbit test and takes only 1 h compared with 24-48 h for the latter method. The reagents required are supplied either in complete kits, with positive, inhibition and negative controls, sterile pipettes and syringes, and labels for identifying the various items, or as 5-ml vials of the lysate and control sets. The Limulus Amebocyte Lysate supplied is reconstituted with the solution being tested and after incubation the presence of endotoxin is indicated by a ring of gelatinized material on the surface of the sample. The test can be used as either a qualitative or quantitative method.

Circle No. 110 on Reader Enquiry Card.

#### Anti-human IgG antisera

FOUR new antisera to human IgG subclasses are now available from Miles: these are antiserum to human IgG1, IgG2, IgG3 and IgG4. Circulating level of IgG subclasses have been associated with autoimmunity, complement-mediated reactions, inhibition of coagulation and numerous other disorders. Antisera to human immunoglobulin subclasses are helpful in classifying monoclonal and polyclonal IgG gammopathies and also hybridomas. A product profile featuring structural diagrams of the four IgG subclasses and product descriptions is available on request.

Circle No. 111 on Reader Enquiry Card.

#### Anti-T lymphocyte

A NEW monoclonal MAS 050 rat IgG antibody against mouse T lymphocytes (clone YBM/29/2.1) is announced by Accurate Chemical & Scientific. This recognizes a monomorphic determinant (Thy-1) on the T lymphocytes of all rat strains. The antibody is secreted by a hybrid cell line produced by the fusion of rat myeloma Y3 Ag 1.2.3 cells with the spleen cells of a rat immunized against mouse bone marrow cells using the technique of Galfre. MAS 050 activates guinea-pig complement and causes lysis of mouse T lymphocytes in a single-stage cytotoxicity test. Its main use is in the separation of mouse T lymphocytes from other cells by complement-mediated lysis, by binding to antibody-coated plastic and fluorescence-activated cell sorting. The antibody can be conjugated directly with fluorochromes or with biotin. It also binds strongly with protein A.

Circle No. 112 on Reader Enquiry Card.

#### **Biologicals**

THE initial product range from Universal Biologicals consists of biologically active peptides from most of the major groups, for example, endorphins, enkephalins, somatostatin and its analogues, bradykinins and parathyroid hormone peptides. Circle No. 113 on Reader Enquiry Card.

#### Serum iron test

NEWLY available from J.T. Baker is a test for serum iron based on the Guanidine/FerroZine method without deproteinization. The test is particularly suitable for automated and semi-automated clinical chemistry instrumentation. To avoid reagent wastage, all components of the serum iron and total iron binding capacity tests are available separately. Major improvements over the conventional Teepol/Bathophenanthroline method are faster reaction time, lower blank values and reduced foaming. In addition, the speed at which lipaemic sera are cleared has been increased.

Circle No. 114 on Reader Enquiry Card.

#### Glycosylated protein test

THE Pierce Glyco-Gel test kit is a research kit for the rapid and reproducible quantitation of glycosylated haemoglobin, glycosylated albumin and non-enzymatic total glycosylated serum protein. The glycosylated proteins are separated by a boronate-agarose affinity chromatography system which is independent of temperature and ionic strength. For glycosylated haemoglobin determinations, c.v. values are typically <2%. The kit contains sufficient pre-packed gel columns, buffers and reagents for 75 quantitative analyses. Circle No. 115 on Reader Enquiry Card.

#### **Electrophoretic markers**

ISOELECTRIC point markers have been introduced by BDH Chemicals. The pl calibration kit (range 4.7–10.6) allows accurate and reproducible measurement of the pH profile of polyacrylamide gels as well as other electrophoretic media such as agarose and other dextran-based polymers. The markers provide a permanent experimental record of the pH profile. Circle No. 116 on Reader Enquiry Card.

#### Platelet control

INTRODUCED by Sarstedt, Inc. as a nonbiological control for testing the accuracy of automatic platelet counters, Thrombo-Control is a suspension of inert plateletsized plastic particles which behave identically to human platelets in all relevant parameters. This material is reported to be stable for up to 1 yr unopened and for 30 days after opening. The suspension is supplied in both a concentrated form for use as a plasma substitute or pre-diluted for automatic platelet counting instruments. The prediluted form eliminates dilution errors. As the product contains no biological material there is no danger of infection.

Circle No. 117 on Reader Enquiry Card.

#### **Interferons**

HUMAN leukocyte interferon (IFN-a; EAB-460) from Enzo Biochem, is produced by normal buffy coat cells induced by Sendai virus and purified by the modified Cantell method to a purity of >106 leukocyte reference units per mg protein. Also available is purified human leukocyte interferon (EAB-451), which is IFN-a (EAB-460) further purified to a specific activity of  $> 2 \times 10^8$  units per mg protein. Both these interferons are calibrated against the NIH international reference standard. Enzo also offers mouse interferon, which is mixture of both IFN- $\alpha$ and IFN-β (EAB-470) prepared in serumfree medium by Newcastle disease virus activation of mouse fibroblasts. Enzo mouse IFN is partially purified and supplied in a sterile lyophilized form, with a specific activity >2 × 10<sup>7</sup> units per mg protein. There is no cytotoxicity on L-929 cells at 105 U ml-1.

Circle No. 118 on Reader Enquiry Card.

# Measuring prostaglandins?

Whether you measure prostaglandins in serum, urine, tissue extracts or even cell culture supernatants, you should know about the Seragen [3H]-RIA kits. Sensitivity, specificity, convenience and reproducibility in prostaglandin measurement are now available in easy to use kits from Seragen.

- · Prostaglandin F<sub>20</sub>
- · Prostaglandin E2
- · Thromboxane B<sub>2</sub>
- · 6-Keto-PGF<sub>10</sub>

High quality antisera to prostaglandins and prostaglandin metabolites are also available.

For further data on the Seragen range of high quality prostaglandin assays and antisera, just call or write to the address below.

SERAGEN, INC., 54 Clayton St., Boston, MA 02122 (617) 265-6004

#### Restriction enzymes

RESTRICTION enzymes and five nucleic acids have been added to the New England Nuclear Nenzymes product line. The restriction enzymes include endodeoxyribonuclease BamHI, endodeoxyribonuclease Bg/II and endodeoxyribonuclease EcoRI. The new nucleic acids are pBR322 (oligo(dG)-tailed) DNA, plasmid DNA molecular weight markers, M13mp7 (oligo(dG)-tailed) DNA, \(\lambda\) DNA (methyldeficient) and exonuclease III (Escherichia coli). Each product is purified to homogeneity as shown by gel electrophoresis and is virtually free from DNA exonuclease, endonuclease, phosphatase and nonspecific protein activities. Also included are DNA/RNA modifying enzymes.

Circle No. 119 on Reader Enquiry Card.

#### Prostaglandin assays

VARIOUS products for immunoassay of prostaglandins have been announced by Seragen Inc. SeraPak immunoassay kits consist of matched components for the radioimmunoassay of prostaglandins  $E_2$  and  $F_{2a}$ . Each kit contains sufficient reagents for 200 assay tubes. SerAb antibodies are high quality, specific antisera for immunoassay of PGE<sub>2</sub>, PGF<sub>2a</sub>, 6-keto-PGF<sub>1a</sub>, PGD<sub>2</sub> and thromboxane B<sub>2</sub>.

Circle No. 120 on Reader Enquiry Card.

#### Isoelectric marker

A SINGLE vial method to mark polyacrylamide gels for isoelectric separations has been devised by United States Biochemical Corporation. Using six cytochrome cs (acetylated), the pl Market Protein Kit may be added with a sample or on a separate gel column as a standard. All six marker proteins are coloured and do not require staining for detection. Complete technical literature is available on request.

Circle No. 121 on Reader Enquiry Card.

#### **Electrophoresis reagents**

A LIST of the main materials used in various electrophoresis methods has been published by Koch-Light Laboratories. The list includes gel components, polymerization initiators and accelerators, buffers, denaturants and reducing agents, dyes and stains, and enzyme detectors. Circle No. 122 on Reader Enquiry Card.

#### **TISSUE CULTURE INCUBATOR**

Modular Incubator Chamber can be used for all types of tissue culture (aerobic, anaerobic). Easy to use! Simply flush with desired gas mixture and place at appropriate temperature. Inexpensive, quantity discounts. billups-rothenberg, inc. pob 977 del mar, ca. 92014-0977 usa (714) 755-3309.

#### Radiochemicals

FOR use in experiments where the presence of potassium acetate is undesirable, L-[35S] methionine (>600 Ci mmol<sup>-1</sup>) from Amersham is supplied in aqueous solution containing 0.1% 2-mercaptoethanol. Also available is [2-<sup>14</sup>C] indomethacin (10-25 mCi mmol<sup>-1</sup>). This a non-steroidal anti-inflammatory drug whch, apart from its major function as a prostaglandin synthetase inhibitor, can also be used in cell cultures to induce synchronous growth, and in membrane studies where its distribution in cells is governed by the pH of intra- and extracellular spaces.

Circle No. 123 on Reader Enquiry Card.

#### Ribonuclease inhibitor

New from Biotec is RNasin, a protein isolated from human placenta tissue which inhibits ribonucleases. This inhibitor helps to maintain the integrity of mRNA, making RNasin useful for cDNA synthesis, in vitro translation, polysome isolation and in vitro transcription. It is stable over a period of months when stored in buffered 50% glycerol solution at -20°C.

Circle No. 124 on Reader Enquiry Card.

#### Chemical catalogue

A NEW chemical catalogue/handbook from Chemical Dynamics, Chemalog 81/82, lists over 8,500 chemicals, biochemicals and reagents and features sections on chromatography, peptides, deuterated solvents, clinical chemicals and optically active compounds. Chemalog 81/82 also includes technical data and references for each item.

Circle No. 125 on Reader Enquiry Card.

#### **HPLC** packing materials

THE range of Nucleosil spherical HPLC packing materials from HPLC technology includes silica, C8, C18, phenyl, CN, NO<sub>2</sub>, NH<sub>2</sub>, N(CH<sub>3</sub>)<sub>2</sub>, OH, cation- and anion-exchange phases. Both 5-µm and 10-um particle sizes are offered. Silicas are available in two pore sizes (50 and 100 Å). A brochure is now available.

Circle No. 126 on Reader Enquiry Card.

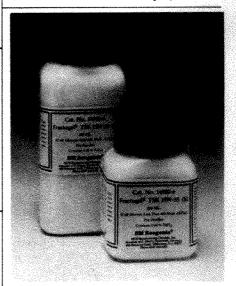

#### Monoclonal antibodies

Six new antibodies to detect cell-surface antigens have been released by Becton Dickinson. These antibodies have a wide variety of applications including indirect immunofluorescence staining, FACS, panning and complement-dependent cytotoxicity. Anti-human Leu 2b is a directly cytotoxic antibody that binds to human T cytotoxic/suppressor cells. Anti-human IgD is specific for IgD in serum and on normal or leukaemic B cells. Anti-mouse Ia.7 (I-E) reacts with specific Ia determinants on mice with  $H-2^{d,k}$  haplotypes. Also available are anti-human Leu 5, antimouse I-Ad and anti-rat x, which is provided as a fluorescein-labelled secondstep reagent for detecting rat antibodies. Circle No. 127 on Reader Enquiry Card.

#### Photoaffinity probes

RECENTLY announced by Schwarz/Mann are two <sup>32</sup>P-labelled photoaffinity probes, [y-<sup>32</sup>P]8-azidoadenosine-5'-triphosphate (<sup>32</sup>P-azido-ATP) and <sup>32</sup>P-8-azidoadenosine-3', 5'-cyclic monophosphate (<sup>32</sup>P-azido-cAMP). These photoaffinity probes are >95% radio-chemically pure by TLC, and are supplied in a methanol solution to increase stability. Non-photoreactive material cannot be detected in these preparations.

Circle No. 128 on Reader Enquiry Card.

#### Gel packing

PACKING material for high performance gel filtration has been announced by MCB. Fractogel TSK is intended particularly for the separation of proteins, enzymes, nucleic acids, oligosaccharides, etc. The packing material consists of a series of hydrophilic semi-rigid spherical gels made from vinyl polymers, designed for lowpressure aqueous gel filtration chromatography. Fractogel TSK will separate sample components in the molecular weight range 100 to 50,000,000 and separations are typically achieved in one quarter the time usually required for conventional soft gels such as dextrans, agarose or polyacrylamides. Fractogel TSK is also stable over a pH range of 1-14 and can be used at pressures up to 100 p.s.i. The gel has a high chemical stability, is resistant to microbial attack and shows minimum gel volume variability during gradient elution. Fractogel TSK is available in 25-40  $\mu$ m and 32-63  $\mu$ m ranges.

Circle No. 129 on Reader Enquiry Card.

#### Phase transfer catalysts

A NEW brochure from Chemical Dynamics Corporation contains a technical discussion of phase transfer catalysis (PTC) theory and practical applications, as well as a complete list of phase transfer catalysts available. Also featured are several new chemicals including prostaglandins, chiral phosphine ligands and peptide reagents.

Circle No. 130 on Reader Enquiry Card.

#### T-cell growth factor

SUPPLIED by Enzo Biochem, human T-cell growth factor (interleukin 2; EAB-451) is produced in concanavalin A-stimulated buffy coat cells. This product maintains the proliferation of mouse and human cells of the T lineage. Human T-cell growth factor is prepared in serum-free minimal essential medium and supplied as a sterile lyophilized powder.

Circle No. 131 on Reader Enquiry Card.

#### Cell culture matrices

New alternative matrices for cell culture are available with a charge surface or a collagen surface. Cytodex 2 and Cytodex 3 from Pharmacia Fine Chemicals are intended for culture of anchorage-dependent cells. Cytodex 2 is a surface-charged bead that is particularly useful for culturing cells of fibroblast-like morphology. Charged groups necessary for cell attachment are present only as a thin layer on the surface of the microcarriers — this gives reduced ion-exchange properties, allowing easy removal of media components for cleaner cell harvesting. Cytodex 3 is a denatured collagen-coated bead, offering a growth matrix more closely approximating the connective tissue surface in vivo. Applications of Cytodex cultures include cellular metabolite response and virus and interferon production.

Circle No. 132 on Reader Enquiry Card.

#### **Electrophoretic blotting**

ADDITIONS to the Bio-Rad line of electrophoresis equipment are the Trans-Blot cell and model 160/1.6 power supply. The Trans-Blot cell is designed to transfer electrophoretically separated DNA, RNA or protein from the gel to an immobilizing matrix in as little as 30 min (compared with 24-48 h for Southern or capillary blotting). Once transferred, the bands are readily accessible for autoradiography, ELISA or fluorescent detection and for preparative elution. The model 160/1.6 power supply has been designed to meet the power requirements of all electrophoretic transfer techniques, with an output of up to 1.6 A essential for the maintenance of a uniform electric field across the large cross-sectional area of the gel.

Circle No. 133 on Reader Enquiry Card.

#### **HPLC** columns

STANDARD 3 Micron Spherisorb columns from Phase Separations generate on average 155,000 plates per m. This, coupled with the fact that it shows negligible decline in efficiency with increasing mobile-phase velocities, makes the 3 Micron Spherisorb column directly applicable to high-speed analysis. Selection of suitable column lengths (5, 10 or 15 cm) with mobile-phase flow rates of 0.5 to 5 ml min<sup>-1</sup> allows maximum flexibility for achieving high resolution and speed.

Circle No. 134 on Reader Enquiry Card.

#### Chromatography matrix

A leaflet describing a new chromatography matrix is available from Bethesda Research Laboratories. RPC-5 Analog matrix has properties similar to those of RPC-5 and is useful for analytical and preparative fractionation of bacterial plasmids and supercoiled viral DNA, cloned DNA fragments and oligomers of ssDNA and RNA, among others. The matrix gives high resolution and allows rapid separations. RPC-5 Analog column chromatography is particularly useful in the purification of plasmids from cellular lysates.

Circle No. 135 on Reader Enquiry Card.

#### **Biological radioiodination**

UNIFORM, non-porous polystyrene beads (Iodo-beads) which have been covalently modified with an oxidizing agent to facilitate the smooth and reproducible iodination of peptides, hormones, proteins and antibodies over a broad range of pH and temperature conditions, are available from Pierce Chemical. To initiate an iodination, Iodo-bead is added to the <sup>125</sup>I-labelling

solution. To terminate the labelling reaction, the bead is removed. Near quantitative labelling with 90-95% protein recovery has been achieved. In addition, the performance of Iodo-beads is not inhibited by azide, detergents, choatrophic agents or high salt.

Circle No. 136 on Reader Enquiry Card.

#### M13 sequencing primer

THE universal M13 sequencing primer, d(TCCCAGTCACGACGT), from New England Biolabs, anneals to the + strand of all M13 lac phages which carry the gene encoding  $\beta$ -galactosidase (M13mp2, mp5, mp7, mp8, mp9 and M13mWJ22). The length and location of annealing of the primer enable reading of the first nucleotide of the inserted fragment while still optimizing the quantity of sequence data obtained from each gel. The 3'-terminal hexanucleotide sequence of this primer was selected because it occurs only once in the M13 genome and assures very low nonspecific priming at other sites on the M13 template.

Circle No. 137 on Reader Enquiry Card.

#### Plant cell enzymes

ENZYMES for use in plant cell biology are now supplied by Genetic Research Instrumentation. These enzymes are Cellulase R10, Pectolyse and Meicelase, and are packaged in 1- or 10-g amounts. This range of plant cell enzymes complements the range of instruments available for plant cell biology, which includes incubators, shakers, freeze dryers, fermenters, centrifuges, laboratory hoods and safety cabinets.

Circle No. 138 on Reader Enquiry Card.

#### **Biochemicals**

PRODUCTS for medical research, from adsorbents and amino acids to venoms and vitamins, are supplied by Koch-Light. The range includes gel permeation media, enzyme immobilization products (Enzacryl), histochemical reagents, hormones, catalysts, carcinogens, nonionic surfactants, nucleosides, buffers and serology reagents.

Circle No. 139 on Reader Enquiry Card.

#### TLC separation medium

A NEW thin-layer chromatography separation medium Fixion, from Chromatronix, differs from other TLC separation media because it separates by ion exchange. Its advantages are high sample throughput, which improves productivity; it handles samples with high salt or acid content; and gives high resolution and efficient separations due to the highly active spherical resin layer. Fixion can be used for one-dimensional separation of amino acids and nucleic acid constituents, determination of essential amino acid content and for the separation of antibiotics, drugs and drug metabolites. Circle No. 140 on Reader Enquiry Card.

.

#### Transcription system

A NEW transcription system from New England Nuclear contains a cell-free extract, derived from HeLa cells, which catalyses the synthesis of mRNA precursors when provided with an exogenous DNA containing a promoter for recognition by the polymerase. This reaction is highly sensitive to the presence of  $\alpha$ -amanitin, indicating an RNA polymerase II-dependent reaction. The system is available with either  $[\alpha^{-32}P]$  UTP or  $[\alpha^{32}P]$  GTP for labelling desired RNA transcripts.

Circle No. 141 on Reader Enquiry Card.

#### Ninhydrin reagent

An advanced formula ninhydrin solution (Nin-Sol AF) has been announced by Pierce Chemical. This is an improvement on the popular ninhydrin-DMSO-hydrindantin formula and offers the advantage of better colour response, linearity and stability.

Circle No. 142 on Reader Enquiry Card.

#### UNIVERSITY OF BRISTOL

DEPARTMENT OF PHYSIOLOGY
Applications are invited for a post of

# POST-DOCTORAL RESEARCH ASSISTANT

to study the effects of reinnervation on motor coordination, using mechanical and electrical recording of muscle.

The post is funded by "Action Research" for a period of two years, and the salary will be in the IA range up to £6.880

Applications, including a full curriculum vitae and the names and addresses of two referees, should be sent to Dr D M Lewis, Medical School, University Walk, Bristol BS8 1TD. (9933)A

#### **BIOCHEMIST**

Tenure track, September, 1982, PhD required. Principal training in Biochemistry, with interest and ability to teach Analytical, Physical (Thermodynamics or Kinetics), Inorganic, or General Chemistry with Quantitative Analysis. Evidence for the following is necessary: potential for excellence in teaching, commitment to the liberal arts, ongoing research plans liberal arts, ongoing research pians and a desire to direct undergraduate research. Initially, principal responsibility will be to teach Biochemistry with laboratory and other upper division chemistry courses commensurate with training. A willingness to help develop a cooperative cell biologybiochemistry program with the Biology Department is important. Department is listed in "Research in Chemistry at Private Undergraduate Colleges" 2nd Ed., Council on Undergraduate Research, 1981.

Send résumé', transcripts of all institutions attended, examples of scholarly work, brief description of research interests, and a discussion of how you might involve undergraduates from a liberal arts institution in your research. Also, arrange for at least three letters of recommendation to be sent to: Dr William J Randall, Chairman, Department of Chemistry, Lewis and Clark College, Portland, Oregon 97219. Closing date for applications is January 15, 1982. Lewis and Clark College is an Equal Opportunity Employer and invites the candidacy of qualified minority persons and women. (NW091)A

INSTITUTE of Cancer Research: A vacancy exists for a Research Officer/Technician in the Institute's Department of Cytogenetics, Royal Marsden Hospital, Fulham Road, SW3. The post is available for two years in the first instance. Current projects in the department include the search for specific chromosome abnormalities in inherited cancers and studies of the action of drugs in vivo and in vitro. Experience in human cytogenetics desirable. Salary grade dependent on age and qualifications. (Research Officer: £5,600 — £7,336 pa) (Technician: £4,958—£6,993 pa) plus London Allowance of £859 pa. Applications in duplicate with the names of two referees to the Secretary, Institute of Cancer Research, 34 Sumner Place, London SW7 3NU, quoting ref. 301/B/11. (9962)A

## UNIVERSITY OF THE WITWATERSRAND,

Johannesburg, South Africa

DEPARTMENT OF ZOOLOGY
CHAIR IN ZOOLOGY

Applications are invited from suitably qualified persons, regardless of sex, race, colour or national origin for appointment to a Chair in Zoology.

It is the University's concern to make an appointment on the basis of outstanding personal attributes rather than field of interest. A particular interest in research, the ability to cross interdisciplinary boundaries and enthusiastic leadership in research will be taken into consideration.

The salary scale attached to this post is  $R20,040\times810$  —  $R20,850\times900$  — R26,250. (£1 = R1.80 approx). Applicants not meeting the requirements for this senior post may be offered appointment at a lower level.

Detailed pamphlets are available on service conditions and the Department of Zoology, and may be obtained from the Secretary, South African Universities Office, Chichester House, 278 High Holborn, London WC1V 7HE, or from the Registrar (Staffing), University of the Witwatersrand, Jan Smuts Avenue, Johannesburg, 2001, South Africa, with whom applications should be lodged not later than 31 December 1981. (9937)A

# ARMAGH OBSERVATORY Armagh, Northern Ireland

Armagh, Northern Ireland
Applications are invited for the post of

#### RESEARCH ASTRONOMER

tenable from 1st April, 1982

Salary will be at an appropriate point on the University Lecturers' scale £6,070 to £12,860 pa according to qualifications and experience.

Applications stating qualifications, publications, research proposals, and names of three referees should be received not later than 31 January 1982 by the Secretary, Armagh Observatory, Armagh BT61 9DG, N Ireland, from whom further particulars may be obtained. (9969)A

#### UNIVERSITY OF QUEENSLAND Australia

# SHORT TERM LECTURER IN PHARMACOLOGY

Applicants should be experienced in both teaching and research. Preference will be given to applicants whose research interests are compatible with the current research programmes of the Department. Applications close: 15 January 1982.

Salary: \$A19,821 — \$26,037 per annum.

Additional information and application forms are obtainable from the Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H0PF. (993))A

# nature

has an immediate vacancy in London for an

# ASSISTANT EDITOR

to work primarily on the assessment of physical science manuscripts.

Essential qualifications:

- \* A good science degree
- \* Some knowledge of the earth sciences
- Some research experience
- \* A sense of literacy
- \* Wide general interests.

Applications, including a full curriculum vitae, should be plainly marked "Job application" and addressed to the Editor, Nature, Macmillan Journals, 4 Little Essex Street, London WC2R 3LF to arrive before 15 December 1981. Secondment for not less than two years would be appropriate.

(9927)A

#### ROYAL OBSERVATORY, EDINBURGH Image and Data Processing Unit

# Scientific Officer

There is a vacancy for an Assistant Computer Manager/Software Specialist in the Image and Data Processing Unit at ROE.

The ROE has responsibility for the development and operation of three major national facilities for the support of research in astronomy: these are the 1.2 M UK Schmidt telescope in Australia, the 3.8 M UK infrared telescope in Hawaii and the cosmos high-speed measuring machine in Edinburgh. The ROE is also one of the major nodes in the Starlink Computer Network for astronomical image processing in the UK. There is a strong and active research group with wide ranging interests and there is close collaboration with the University of Edinburgh.

#### DUTIES:

The successful applicant will assist in the management of the computing facilities at the ROE. These computing facilities comprise on-site GEC 4082 and DEC VAX 11/780 mainframe systems plus links to remote central computing facilities. Duties will included the development, documentation and maintenance of scientific applications software, assistance in the efficient running of the computr systems and user liaison.

#### **QUALIFICATIONS AND EXPERIENCE:**

Candidates should possess a degree or equivalent in mathematics or one of the sciences. Some experience of computer systems and programming in a high level language is essential. Experience of hardware and systems software would be desirable but is not essential.

The starting salary will be in the range £5,176 - £6, 964.

Application forms may be obtained from: Mr. R.L. Wison, Personnel Section, Royal Oservatory, Blackford Hill, Edinburgh. EH9 3HJ. Tel: 031-667 3321.

Application forms should be returned by 18 December 1091.

(9968)A

#### MANCHESTER AREA HEALTH AUTHORITY (TEACHING)

#### POST OF DIRECTOR

Christie Hospital & Holt Radium Institute, Paterson Laboratories

To take up post in June 1983 on the retirement of Professor L G Lajtha.

The Director is the Scientific and Aministrative Head of the Paterson Laboratories containing ten Divisions and approximately 180 staff with responsibility to maintain and develop further Research Programmes which are mainly supported by the Cancer Research Campaign.

The Director will be offered an Honorary Professorship in Experimental Oncology at Manchester University.

Appropriate MRC salary scale and Conditions of Service. The NHS or USS Superannuation Scheme will apply.

Job description and further details available from the Area Personnel Officer, Manchester Area Health Authority (Teaching), Mauldeth House, Mauldeth Road West, Chorlton, Manchester M21 2RL (Tel: 061-881 7233 ext 219).

Professor Lajtha will be please to discuss the appointment with intending applicants. Tel: 061-445 8123.

Applications to be returned to the Chairman, Manchester Area Health Authority (Teaching), Mauldeth House, Mauldeth Road West, Choriton, Manchester M21 2RL by 4.1.82. (9942)A

#### DEPARTMENT OF ZOOLOGY University of California, Davis ASSISTANT PROFESSOR

Applications are invited for a tenure-track position at the Assistant Professor level for September 1982. A strong, independent research program is expected; fields of particular interest include, but are not limited to, evolutionary biology, marine or behavioral ecology, and environmental physiology. Preference will be given to candidates able to teach invertebrate zoology at the upper-division level. The appointee may also teach a one — quarter course in introductory biology and will have the opportunity to develop courses and/or seminars in his/her area of expertise.

seminars in his/her area of expertise.

Persons wishing to apply should send a curriculum vitae, reprints of published work, a description of research program and future plans, a summary of teaching experience and capabilities including evaluations if available, and three letters of recommendation to:

Dr. Arthur M. Shapiro, Chairman, Search Committee, Department of Zoology, University of California, Davis, CA 95616.

Final Date for receipt of applications is *February 15, 1982*. The University of California is an equal opportunity/affirmative action employer. (NW101)A

#### RESEARCH POSITION

(C1, Hochschulassistent) in antiinfective immunology available Applicants (PhD or MD) should have a keen interest and experience in antiinfective immunology (T cell cloning, receptor analysis, biochemistry of mediators).

This position allows ample time for research; in addition, participation in teaching lectures and courses in medical microbiology as well as work in the routine laboratory are obligatory. In the latter field, no special experience is required.

For further information contact: Prof. Dr med. Helmut Hahn, Institute für Medizinische Mikrobiologie der Freien Universität Berlin Hindenburgdamm 27, D-1000 Berlin 45, West Germany. (W497)A

# THE INSTITUTE FOR ADVANCED STUDY

will have several openings for members in theoretical physics and astrophysics for the academic year 1982-83. The positions are at a post-doctoral or higher level and applicants will be selected on the basis of their ability to do research in the areas of elementary particles, mathematical physics, astro-physics, plasma physics, general relativity and statistical mechanics. Preference is given to candidates who have received their PhD within the last year or two.

Postdoctoral members frequently collaborate with each other, with faculty members at the Institute or Princeton University, and with researchers at other institutions.

Appointments ae usually for no more than two years and support is typically full salary for postdoctorals and half salary for more senior persons. Women and minorities are encouraged to apply.

For more information write to Ms Valerie Nowak, Administrative Officer, School of Natural Science, The Institute for Advanced Study, Princeton, New Jersey 08540. Applications should be received by December 15, 1981. (NW1006)A

PROFESSOR. ASSISTANT Biochemistry-Molecular Biology. Tenure-track 12 month position. Candidates should show outstanding potential for research and be interested in team teaching biochemistry and offering a graduate course in proteins and enzymes. Areas of research interest can include (but are not limited to) membrane biochemistry, enzyme regulation or regulation of gene expression. Post-doctoral experience is desirable. This position will be approximately 75% research with an appointment in the Experiment Station. Please send curriculum vitae, a short statement of research interest, and three letters of reference by 15 February 1982 to Dr Wayne E Magee, Head, Department of Bacteriology and Biochemistry, College of Agriculture, University of Idaho, Moscow, Idaho 83843. Affirmative Action/Equal Opportunity Employer. (NW107)A

#### UNIVERSITY OF LEICESTER PHYSICS RESEARCH PhD

The Department of Physics at Leicester offers research opportunities leading to the degree of Doctor of Philosophy in the following areas:

CONDENSED MATTER PHYSICS
IONOSPHERIC PHYSICS
NUCLEAR ELECTRONICS
QUANTUM MOLECULAR
PHYSICS
THEORETICAL PHYSICS

X-RAY ASTRONOMY

The Department has very active, well-balanced research programme which receives a high level of support from both government and industry. In addition to in-house research, collaborative projects are undertaken involving other institutions in the UK and abroad. There are excellent workshop and computing facilities.

Further details and application forms may be obtained from Dr C Norris, Department of Physics, University of Leicester, University Road, Leicester LE17RH. (9948)A

# Readvertisement University of London British Postgraduate Medical Federation CARDIOTHORACIC INSTITUTE CARDIAC MUSCLE RESEARCH UNIT PHYSIOLOGIST/BIOPHYSICIST/ PHARMACOLOGIST (Post-doctoral)

A vacancy exists for a post-doctoral scientist to work on a project utilising intracellular ion-selective microelectrodes in cardiac muscle. Previous experience in electrophysiology would be an advantage. The appointee will work in a multi disciplinary team with extensive and varied research interests relating to the heart.

Salary on appropriate point on Research Assistant Scale 1A, currently £6,070 — £10,575 plus £967 London Weighting Allowance. Universities Superannuation scheme applies.

Further details from Dr Poole-Wilson, (tel: 01-486 3043). Applications with full curriculum vitae, list of publications, names and addresses of three referees to Secretary, Cardiothoracic Institute, Fulham Road, London SW3 6HP to arrive no later than 4th January 1982.

# UNIVERSITY OF CAMBRIDGE DEPARTMENT OF EARTH SCIENCES RESEARCH ASSISTANT IN STABLE ISOTOPE GEOCHEMISTRY

A graduate or post doctoral research asssistant with a background in mass spectrometry or stable isotope techniques is required to perform a D/H ratio study designed to investigate the possible occurrence in chondritic meteorites of material synthesised by ion molecule reactions in dark interstellar clouds. The appointment is for 2 years with a salary up to £7,700 pa.

Applications including a CV and names of referees to Dr C T Pillinger, Planetary Sciences Unit, Department of Earth Sciences, Cambridge CB2 3EQ, telephone (0223) 355463 ext 283 as soon as possible. (9955)A

#### UNIVERSITY OF PITTSBURGH ASSISTANT PROFESSOR BIOLOGICAL SCIENCES

The Department of Biological Sciences invites applications from highly qualified individuals with a strong research commitment in one or more of the following areas: theoretical ecology, population genetics, evolutionary ecology, physiological ecology, aquatic ecology, microbial ecology or behavioral ecology. A curriculum vitae, list of publications, names of at least three references, and a summary description of your current research program and future plans should be sent to: M Sussman, Chairman, Department of Biological Sciences, University of Pittsburgh, Pittsburgh, PA 15260. Starting date after July, 1982. Closing date for applications: January 29, 1982.

The University of Pittsburgh, acting in the spirit and the letter of Affirmative Action regulations, actively encourage applications from women, minority members, and other individuals covered by the mandates of Title IX. (NW110)A

#### KING'S COLLEGE HOSPITAL MEDICAL SCHOOL

(University of London) Denmark Hill, London SE5 8RX

#### A GRADUATE RESEARCH ASSISTANT

is required to join a team in the Liver Unit, investigating lymphocyte population and suppressor function in children with chronic liver disease. Previous experience in immunology desirable.

The appointment will be for one year in the first instance. Salary on the Research Assistant 1B scale £5,285 — £6,475 plus £967 London Weighting Allowance, according to age, experience and qualifications. Applications, in duplicate, including the names of 2 referees should be sent to the Secretary of the Medical School at the above address, no later than 17 December 1981. (9938)A

#### THE UNIVERSITY OF MISSISSIPPI MEDICAL CENTER

DEPARTMENT OF PHARMACOLOGY AND TOXICOLOGY

#### **CHAIRMANSHIP**

Candidates for the chairmanship of the Department of Pharmacology and Toxicology are being sought. Qualifications include an established reputation in research and teaching and the ability to direct a department with an active graduate program and teaching responsibilities for medical, dental, and nursing students.

Applicants should submit curriculum vitae, list of publications, description of research plans, and names of three references by March 1, 1982, to: Dr Dennis J O'Callaghan, Chairman, Search Committee, Department of Microbiology, University of Mississippi Medical Center, 2500 North State Street, Jackson, Miss. 39216. The University of Mississippi Medical Center is an equal opportunity employer, M/F/V/H.

(NW092)A

#### CSIRO

#### **AUSTRALIA**

# **Research Scientist**

(2 Positions)

#### Division of Food Research North Ryde, New South Wales

CSIRO has a broad charter for research into primary and secondary industry areas. The Organisation has approximately 7,500 employees — 2,700 of whom are research and professional scientists — located in Divisions and Sections throughout Australia.

**General:** The research program of the Division includes many aspects of the physical and biological sciences related to the handling, processing and storage of foods and to the needs of the food industry and the consumer.

#### 1. Ref. A2611

Field: Microbiology (microflora of the gut)

**Duties:** To participate in and supervise research on the influence of diet on the microbial flora of the human gut. The study will include the influence of individual foods and food additives and of prior processing of foods on the gut flora and, in turn, the effects of this flora on the intestinal metabolism and subsequent absorption of dietary components.

Qualifications: A Ph.D. degree or equivalent, with experience in the biochemistry and microbiology of the gut microflora, anaerobic techniques, expertise in chromatographic analyses and demonstrable research ability.

#### 2. Ref. A2557

Field: Plant Physiology/Biochemistry

**Duties:** To participate in research program into the regulation of protein synthesis in the cells of mature plant tissues. The program includes the *in vitro* translation of isolated ribonucleic acids, identification by immunological and other techniques of translation products, the cloning of DNA and the measurement of abundances of specific messenger RNAs.

Qualifications: A Ph.D. degree, or equivalent, in Plant Physiology, Biochemistry or other relevant field together with demonstrable research ability. Experience in nucleic acid chemistry and biochemistry is essential and a knowledge of the physiology of ripening and senescence in plants is desirable.

Tenure: Indefinite with superannuation (both positions).

Applications: Stating full personal and professional details, the names of at least two referees, and quoting reference numbers A2611 or A2557, should reach: The Chief, Division of Food Research, CSIRO, PO Box 52, North Ryde, NSW 2113, Australia by 31 December 1981.

#### **Royal Postgraduate Medical School**

(University of London)

Applications are invited for a five-year appointment as

# Lecturer (non-clinical) in the Department of Immunology

A post-doctoral science graduate with experience in immunochemistry is sought. The successful applicant will contribute to the setting up of a postgraduate immunology course. Experience in teaching and organisation of courses is essential. Appropriate technical support will be provided.

There will also be opportunities for research in a well equipped department. The particular interests of the department include major histocompatibility systems, and their relationship to immunologically mediated diseases and organ transplantation, the study of patients with eosinophilia and experimental models of filiariasis. Salary on the scale £6,070 to £12,860 p.a. plus £967 London Allowance.

Applications, enclosing six copies of curriculum vitae and naming three referees, to the Deputy Secretary, Royal Postgraduate Medical School, Hammersmith Hospital, Ducane Road, London W120HS. (01-743 2030 ext. 263) from whom further particulars can be obtained. Closing date 15 January 1982. (9950)A

# **LELUS**

pioneer in bioindustry since 1971, is currently seeking innovative professionals in the following areas:

- Molecular genetics
- Nucleic acid biochemistry
- Molecular virology
- Cloning and expression of eukaryotic genes
- Microbial physiology
- Analytical chemistry
- Enzymology
- -Chemical catalysis
- -Protein chemistry
- -Plant cell genetics
- Biochemical engineering
- Process engineering
- Instrumentation Design

We invite you to submit your resume in confidence to:

> **CETUS CORPORATION BOX NKLH** 600 Bancroft Way Berkeley, CA 94710 (415) 549-3300

(NW086)A

#### ASSOCIATE DEAN FOR **CURRICULUM UNIVERSITY OF MASSACHUSETTS** MEDICAL SCHOOL

Candidate for this position should have a PhD or MD degree. Responsibilities will include the planning of a new curriculum and its ongoing evaluation; should have a strong interest and ability in teaching medical students; should have administrative skills, and be able to relate to large numbers of faculty; will work closely with existing faculty and student committees in the areas of educational policy and curriculum design.

In the organizational structure, the Associate Dean for Curriculum will report to the Academic Dean. The individual will be a member of the Educational Policy Committee and will be responsible for chairing a group of working subcommittees of faculty and students, which subcommittees will design the details of the new curriculum using guidelines recommended by the Educational Policy Committee. The Associate Dean for Curriculum will be responsible for the implementation of this new curriculum including matters such as scheduling, allocation of time to various learning activities, allocation of responsibility to various chairpersons and providing ample liaison and communication with faculty and students. Ongoing evaluation and efficacy should be monitored through contact with the student committee on evaluation of courses, by long term follow-up through feedback from house officer programs, and by any other methods which are appropriate.

This position offers an outstanding opportunity to an individual who wants to make his or her work in the field of medical education, in a school whose excellent faculty is clearly in favor of curriculum

change.

University of Massachusetts Medical Center Interested persons should send résumé to: John P. Howe, III, MD., Vice Chancellor/Academic Dean, University of Massachusetts Medical School, 55 Lake Avenue North, Worcester, MA 01605.

An Affirmative Action/Equal (NW114)A

#### **UNIVERSITY OF** LIVERPOOL

#### DEPARTMENT OF BIOCHEMISTRY RESEARCH ASSISTANT

Applications are invited from raduates in Biochemistry or Microbiology to work on a project investigating the production of proteinase inhibitors by Streptomyces. The project is funded by the SERC and is under the supervision of Dr R J Beynon.

The appointment will be made as soon as possible at an initial salary of £5,285 pa.

Applications, together with the name of two referees, should be received not later than 14th December, 1981, by The Registrar, The University, PO Box 147, Liverpool, L69 3BX, from whom further particulars may be obtained. Quote Ref: RV/906/N. (9936)A

#### KING'S COLLEGE HOSPITAL MEDICAL **SCHOOL** (University of London)

Denmark Hill, London SE5 8RX

#### A POST-DOCTORAL RESEARCH ASSISTANT

is required to join a team in the Liver Unit, investigating lymphocyte cytoxicity to hepatocytes in the pathogenesis of chronic liver disease in children and adults. Experience in lymphocyte culture techniques and immunofluorescene would be an advantage

The appointment will be for one year in the first instance. Salary on the 1A scale £6,070 — £7,290 plus £967 London Weighting Allowance, according to age, experience and qualifications. Applications, in duplicate, including the names of 2 referees should be sent to the Secretary of the Medical School at the above address, no later than 17 December 1981. (9940)A

#### ST MARY'S HOSPITAL MEDICAL SCHOOL (University of London) Norfolk Place, London W2 1PG

#### DEPARTMENT OF VIROLOGY RESEARCH ASSISTANT OR MEDICAL LABORATORY

SCIENTIFIC OFFICER

required for a grant-funded, temporary position for one year to assist in program of comparative analysis of poxvirus genone structure and function. Applicants should be familiar with DNA technology relevant to restriction analysis and experience in tissue culture/Animal virology techniques would be advantageous. Appointment will start January 1982 or soonest and salary will be appropriate to qualifications.

Enquiries to Dr L Archard (01) 723 1252 ext 236. Applications in form of full cv and names and addresses of two to Assistant Secretary (Personnel) at above address not later than 14.12.81. Please quote Ref: RA/LA. (9963)A

#### The Flinders University of South Africa School of Physical Sciences

Applications are invited from persons holding a PhD degree in chemistry, physics or ceramics engineering for appointment as:

#### Research Fellow/ Associate in the **Ceramics Laboratory**

The appointee will investigate the chemical physics of interfacial reactions between noble metals and ceramic oxides. Emphasis is placed on impedance spectroscopy of faradaic charge transfers and phases, electron and optical microscopy, and characterisation of reaction products for thin noble metal films on single crystal oxide subtrates.

Available equipment includes a Solartron FRA with interface, a MINC 11/23 computer, an extensive range of electrochemical equipment for AC and DC measurements and access to Prime 750 and DEC system 10 computers. The Group is well supported by engineering and electronic workshops.

The appointment will be for one year in the first instance. Salary range \$A17,083 — \$A19,570, depending on qualifications and experience.

Further information may be obtained by contacting Associate Professor H. J. De Bruin (telephone 08-275 2191: telex 89624 Flindu).

Applications including a curriculum vitae with full details of qualifications and experience and the names of three referees of whom confidential enquiries may be made, should be lodged with the Registrar, The Flinders University of South Australia, Bedford Park, S.A. 5042 Australia, by 4 January, 1982. (9944)A

#### UNIVERSITY OF GLASGOW

DEPARTMENT OF MATERIA MEDICA, STOBHILL GENERAL HOSPITAL, GLASGOW RESEARCH ASSISTANT

There is a vacancy from 1st January, 1982 for a Research Assistant to join a pharmacological project investigating the role of peptide neurotransmitters — enkephalins, angiotensin and Substance P — in central regulation of baroreceptor and chemoreceptor reflex function. A background in pharmacology or related neuroscience is desirable. The post is available for 18 months and is supported by the Scottish Home and Health Department; starting date by arrangement. Salary will be within £6,070 to £7,290 on Range 1A of the scales for Research and Analogous Staff. The post is superannuated.

Further information from, and applications (curriculum vitae and names of two referees) to. Professor John Reid, Department of Materia Medica, Stobbill General Hospital, Glasgow, within 7 days.

In reply please quote Ref. No. 4870M. (9970)A

#### THE CHINESE UNIVERSITY OF **HONG KONG**

Applications are invited for the following posts tenable from August, 1982:

 Lecturer in Biology (Botany) —
 Applicants should have special competence in genetics or cytology and be able to teach basic botanical courses

2. Lecturer in Chemistry - To teach Physical Chemistry courses with laboratory supervision and to develop a research programme. (Applicants should have some working knowledge of Chinese, and forward a short research proposal (not over 2 pages) listing equipment and support required).

General Requirements: Applicants should have a higher degree (preferably a PhD) in the relevant field, with appropriate university teaching and/or research experience.

Conditions of Service: Annual salary: HK\$112,980 — HK\$128,220 by 2 increments BAR 135,840 — 189,060 by 7 increments. Exchange rate approximately £1 = HK\$10.5. Starting salary will depend on qualifications and experience. Terms of service include include superannuation (University 15%, appointee 5%), medical benefits, education allowance for children long leave, housing benefits for those whose annual salary is \$120,600 and above and, for those employed on overseas terms, accommodation on campus (at a rental equivalent to 7 ½ % of salary) and air passage as well.

Application Procedure: Further information concerning Terms of Service and Application Forms are obtainable from the Personnel Section, The Chinese University of Hong Kong, Shatin, New Territories, Hong Kong. Completed application forms together with one t of major publications and copies of testimonials should be returned before January 31, 1982. Please mark 'Recruitment' on cove

(W508)A

#### YOUNG INVESTIGATORS **MOLECULAR BIOLOGY OF HUMAN HEMOPHILIAC FACTOR**

Immediate opening for three young investigators or postdoctoral fellows to address central issues in the molecular biology, biosynthesis, structure and function of the human hemophiliac factor protein. Candidates must have demonstrated accomplishment in applicable areas protein biochemistry, primary structure analysis, or protein biosynthesis and in vitro translation. Experience in trace protein purification and use of immunochemical methodology is desirable.

Appointments are for two years with reappointment dependent upon accomplishment and progress. Salaries are competitive and appropriate to the level of experience and appointment. Starting dates as soon as possible after Jan 1, 1982. Inquiries accompanied by curriculum vitae to Dr T S Edgington, Research Institute of Scripps Clinic, La Jolla, (NW096)A CA 92037.

#### KING'S COLLEGE HOSPITAL MEDICAL **SCHOOL**

(University of London) Denmark Hill, London SE5 8RX

#### RECENT SCIENCE **GRADUATE**

required as research assistant to join a team studying genetic aspects of immune responses in liver disease. No previous experience is necessary as the successful applicant will be trained in tissue typing techniques. The appointment will be for one year in the first instance. Salary £5,285 + £967 London Weighting Allowance, according to age, experience and qualifications.

Applications, in duplicate, including the names and addresses of 2 referees should be sent to the Secretary of the Medical School, at the above address, no later than 17 (9939)A December 1981.

#### IMPERIAL CANCER RESEARCH FUND TECHNICIAN/RESEARCH **OFFICER**

required to assist in a programme of research involving the development of reagents for the diagnosis and treatment of a variety of human tumours. These studies will involve extensive use of monoclonal antibodies and experience in tissue culture and/or immunology would be an advantage. The appointment is based at our Medical Oncology Unit, St Bartholomew's Hospital, London EC1 and the Institute of Child Health, Great Ormond Street Hospital. HNC/Degree. Salary range £6,045 to £8,423

For further information and Application form write to or telephone Miss S M Hurley, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2 on 242 0200 ext 305. Quoting reference 12/82

(9930)A

#### ASSISTANT PROFESSOR **OF ANATOMY**

Applications are invited from neurobiologists who have at least two years of postdoctoral research training and who are willing to acquire a suitable background for teaching gross anatomy to professional students. Research interests in neuroendocrinology, developmental neurobiology or sensory neurophysiology or sensory neurophysiology are particularly welcome. If a candidate's research involves primates, a joint appointment with the Yerkes Regional Primate Research Center can be considered. Deadline for receipt of applications is January 1, 1982.

Send curriculum vitae, names of four referees and desciption of specific research plans to; Dr J Sutin, Chairman, Department of Anatomy, Emory University school Medicine, Atlanta, Georgia 30322 Emory University is an Equal Opportunity/Affirmative Action (NW094)A Employer.

#### **POSITION OPEN IN EGYPT**

**Laboratory Director for the Central Laboratory** Located on Campus of Cairo University in Cairo, Egypt

#### Agricultural Development Systems (ADS): **Egypt Project** University of California

Qualifications:

Candidate must have PhD or equivalent in a branch of Plant Biology or Plant Chemistry; experience in scientific investigation related to biological, chemical, and physical analyses; knowledge of use and maintenance of scientific laboratory equipment; experience with training and supervision of technical personnel; and ability to administer a scientific laboratory.

Responsibilities and Duties:

- Organize and supervise the establishment of the laboratory administrative and research subunits. This includes the recruitment of qualified personnel and the preparation of the physical facilities.
- Prepare existing laboratory and equipment for immediate use Supervise the operation and maintenance of the Central
- Laboratory.
- Establish a training program for ADS scientists and visiting scientists and technicians.
- Implement the research instrumentation requirements of the Central Laboratory and, eventually, satellite laboratories elsewhere in the country.
- Advise, consult, and assist ADS project participants in the planning and execution of the research programs.

Annual Base Salary:
Depends upon qualifications. Salary is supplemented by an overseas 'post differential" (currently 15%). Benefits are in accordance with University and AID regulations. The term of appointment is approximately two years.

Final filing date January 31, 1982, or until filled.

Apply to: David Robinson, Agricultural Development Systems: Egypt Project, University of California, Davis, Ca 95616.

The University of California is an equal opportunity/affirmative action employer.

# BIOTECHNOLOGY

Codon's facility located on the San Francisco peninsula is staffed and fully equipped to undertake applied research in nucleic acid chemistry, molecular biology, microbiology, immunology and protein chemistry.

The proximity to several pioneer institutions in recent advances in genetic engineering make the scientific climate in the area highly desirable.

If you wish to join Codon's expanding staff of highly qualified personnel, please send résumé in confidence to:

> Codon \* 430 Valley Drive Brisbane, CA 94005.

> > (NW109)A

# Biochemist / Pharmacologist

Eli Lilly & Co is one of the world's largest producers of ethical pharmaceuticals, animal health and agro-chemical products. At our U.K. Research Centre, situated near Camberley in Surrey, we are actively engaged in basic research on a variety of projects.

We currently have a vacancy for a Biochemist Pharmacologist to work in our Immunology Group on a project dealing with biochemical aspects of membrane function. We are seeking someone with a graduate level or equivalent qualification and preferably, 2-3 years' experience in lipid biochemistry, membranes or enzymology.

For this position a competitive salary is offered together with a non-contributory pension and life assurance scheme, subsidised BUPA, 21 days' holiday, flexible working hours and relocation expenses where applicable.

Interested candidates should telephone or write to Miss S M Smith, Personnel Manager, by the first week in December and interviews will be carried out early in January.

#### HILL FARMING RESEARCH ORGANISATION Information Officer/Librarian

Applications are invited for the post of Information Officer/Librarian. Candidates should have a degree or HNC or equivalent in Information Science or Librarianship or equivalent experience and preferably with an additional qualification in Science or Agriculture.

The post will involve various aspects of information and public relations work, editorial duties and responsibility for an efficient information retrieval service and library.

Salary: Within the scale £7,467 to £9,184.

Other Conditions: Non-contributory superannuation scheme; Annual leave - 22 days per annum.

Further particulars and application forms may be obtained from the Secretary, Hill Farming Research Organisation, Bush Estate, Penicuik, Midlothian EH26 0PY to whom they should be returned not later than 31 December 1981. Please quote reference A/6/264

(9949)A

#### **BROOKLYN BOTANIC GARDEN** RESEARCH PLANT **PHYSIOLOGIST**

Position at the Brooklyn Botanic Research Center, Ossining, New York. Research program involves innovative approaches to basic and applied research mostly with a horticultural bias. Interest and expertise in tissue culture highly desirable. PhD required.

Send, in confidence, curriculum vitae, statement of research interests, salary history, three letters of reference, graduate transcripts and publications to: Dr Stephen K M Tim, Director of Scientific Affairs, 1000 Washington Avenue, Brooklyn, New York 11225. An Affirmative Action/ Equal Opportunity Employer. (NW093)A

#### UNIVERSITY OF NEWCASTLE UPON TYNE

DEPARTMENT OF PHARMACOLOGICAL SCIENCES TEMPORARY CLINICAL/ **NON-CLINICAL** RESEARCH ASSOCIATE

Applications are invited from suitably qualified candidates with experience in neurophysiology for a temporary post of Research Associate to join a team studying somatosensory evoked potentials for the objective measure-ment and differential diagnosis of chronic pain. This project will provide opportunities for experience in a clinical psychopharmacology laboratory and/or a Pain Relief Clinic. This temporary appointment will start as soon as possible and is available fro three years. Com-mencing salary according to age, qualifications and experience up to £10,360 pa on the scale £8,070 — £14,300 pa for medically qualified candidates, or £9,335 pa on the scale £6,070 — £10,575 for non-medical candiates.

Applications giving names of two referees should be submitted as soon as possible and not later than 18th December 1981 to Professor J W Thompson, Clinical Psychopharmacology Unit, 13 Framlington Place, Newcastle upon Tyne NE2 4AB, from whom further information can be (9941)A

#### BIOPHYSICIST

tenure track position will be available in Biophysics at the University of Illinois at Urbana-Champaign, effective Fall 1982. The position is expected to be at the assistant professor level. It is anticipated that the successful applicant will carry out research and teaching in biophysics, in the general area of biomolecular structure. Candidates should have a PhD degree and some postdoctoral experience. Salary is netotiable. Please send your curriculum vitae by February 15, 1982 to Dr Thomas G Ebruary 15, 1982 to Dr Itionias of Ebrey, Chairman of Biophysics Search Committee, 524 Burrill Hall, 407 S Goodwin, University of Illinois, Urbana, IL 61801 (Tel: [(217) 333-2015]. The position is available subject to budgetary approval. An Equal Opportunity and an Affirmative Action Employer an Affirmative Action Employer (NW100)A

**UNIVERSITY** OF BIRMINGHAM Faculty of Medicine and Dentistry DEPARTMENT OF CARDIOVASCULAR MEDICINE **POSTDOCTORAL** RESEARCH FELLOW

Applications are invited for the above position to work on the biochemical role of the contractile and regulatory proteins in the mammalian heart. The successful applicant will join the Molecular Cardiology Unit within the Department investigating the mode of action of myosin isoenzymes in relation to cardiac function. Particular emphasis is placed on the study of the human myocardium and the molecular changes occurring during development and cardiac disease. Experience in protein separation and modification techniques preferable.

The post is available for 2 years and 5 months, supported by the MRC, at a starting salary between £6,070 to £6,880 plus superannuation.

Further information from Dr P Cummins, Cardiovascular Medicine, University of Birmingham B15 2TH (021-472 1311 ext 224).

Applications (three copies) to Assistant Registrar, Medical School, Birmingham B15 2TJ by 14 December 1981. Please quote ref RF/Card/481. (9958)A RF/Card/481.

#### The University of Arizona Seeks a Dean of the Faculty of Science

The University of Arizona is creating a new College of Arts and Sciences to be composed of the Faculties of Fine Arts, Humanities, Sciences, Social and Behavioral Sciences. The Faculty of Sciences will consist of about twelve departments including mathematics, the physical, and biological sciences in a growing series of a major programs on our campus. The administration recognizes the scientific achievements of its faculty and now desires to enhance both the cohesion and leadership in these disciplines by means of the new organization.

The University is seeking candidates for the Dean of Faculty of Science who have the highest qualifications, both in academic and administrative accomplishments. The appointment will also include a professorship with tenure. The Dean will be responsible for academic, administrative and budgetary activities within his faculty. and will report to the Provost of the College of Arts and Sciences. All inquiries, applications, and nominations should be sent to the Office of the Executive Vice President no later than February 1, 1982.

A. B. Weaver, Executive Vice President, University of Arizona, Administration 512, Tucson, Arizona 85721.

Equal Opportunity/Affirmative Action Employer.

#### THE UNIVERSITY OF **NEBRASKA**

Lincoln

Molecular Genetics

#### ASSISTANT/ASSOCIATE **PROFESSOR**

tenure-leading, August, 1982. Conduct an active research program on molecular aspects of gene organization, gene replication or gene expressing. Teaching res-ponsibilities will include microbial genetics graduate course and molecular biology or microbiology course. \$19,500 minimum salary for academic year. Research initiation funds available.

Send curriculum vitae, summary of research interests and names of three referees by February 1 to: Dr S D Schwartzbach, School of Life Sciences, University of Nebraska-Lincoln, Lincoln, Nebraska 68588-0118. Afirmative Action/ Equal Opportunity Employer (NW098)A

#### **UNIVERSITY OF HONG KONG**

#### **CHAIR OF CHEMISTRY**

Applications are invited for the Chair of Chemistry which will fall vacant in January 1983 following the resig-nation of Professor D S Payne.

Annual salary (superannuable) will be within the professional range and not less than HK\$250,920 (£1 HK\$10.60 approx).

At current rates, salaries tax will not exceed 15% of gross income. Housing benefits at a rental of 7½% of salary, education allowance, leave and medical benefits are provided.

Further particulars and application forms may be obtained from the Secretary General, Association of Commonwealth Universities (Appts), 36 Gordon Square, London WC1H OPF, or from the Appointments Unit, Secretary's Office, University of Hong Kong, Hong Kong.

The closing date for application is 31 December 1981. (9952)A

UNIVERSITY OF GEORGIA DEPARTMENT OF BIOCHEMISTRY, **BIOLUMINESCENCE LABORATORY** 

#### Athens, GA 30602 RESEARCH ASSOCIATE

Immediate opening in a project to study the structure and other properties of proteins involved in the bioluminescence of luminous bacteria (Lumazine protein; J Biol Chem (1980) 255, 8804). Recent PhD in Chemistry or Biochemistry, some experience in protein chemistry or physical biochemistry would be an advantage. Inquiries to Dr John Lee. (NW095)A

#### PUBLIC HEALTH LABORATORY SERVICE **BOARD** PHLS CENTRE FOR APPLIED MICROBILOGY AND RESEARCH **PATHOGENIC MICROBES** RESEARCH LABORATORY **BASIC GRADE**

A graduate in microbiology is required to join a group studying the pathogenesis of Legionnaires' disease in experimental animals. The work will include isolation and cultivation of Legionella pneumophila from tissues.

MICROBIOLOGIST

The appointment will be as Basic Grade Microbiologist in the salary range £5,667 — £6,745.

#### JUNIOR 'B' MLSO

Required to assist with studies on experimental Legionnaires' disease. The salary will be in the range £3,120 - £4,268.

Both these posts are funded by the Medical Research Council and will run for one and half years.

Further details of the posts may be obtained from Dr A Baskerville. Tel: 0980 610391.

Applications including curriculum vitae and the names and addresses of two referees should be sent to Mrs M Bushby, Personnel Officer, PHLS Centre, For Applied Microbiology and Research, Porton Down, Wilts SP4 0JG. Closing date 11th SP4 0JG. Cl December, 1981. (9943)A

- a leader in the commercial application of biotechnology is seeking:
- Ph.D.s in molecular biology with experience and interest in virology and infectious diseases. Preference will be given to individuals with a broad background which includes recombinant DNA techniques and immunological characterization of viral antigens. Positions are available at the Sr. Scientist, Scientist, and Postdoctoral levels.
- •Ph.D.s in biochemistry or molecular biology with 3-5 years' postdoctoral experience, preferably in DNA cloning, expression and eukaryotic gene regulation for pharmaceutical use.

Applicants should send their resumes in confidence to:

> **CETUS CORPORATION BOX NJN** 600 Bancroft ₩ay Berkeley, CA 94710 (415) 549-3300

#### TWO MOLECULAR **GENETICISTS**

#### Department of Molecular and **Population Genetics** University of Georgia

The University of Georgia is seeking two molecular geneticists for tenure track positions at the Assistant Professor level, beginning fall 1982. For one position, preference will be given to candidates with interests in prokaryotic or viral genetics. For the other position, preference will be given to a eukaryotic molecular geneticist; one area of interest is molecular evolution. However, qualified candidates in any area of molecular genetics will be considered. Candidates will be expected to maintain an active research program and to teach at the graduate and undergraduate level. The Department of Molecular and Population Genetics is a new department with 12 faculty members and strong research programs in molecular genetics and population genetics.

Applicants should send curriculum vitae and names and addresses of four references to Dr. Norman Giles, Chairman, Molecular Geneticist Search Committee, Department of Molecular and Population Genetics, University of Georgia, Athens, Georgia 30602. Screening of applicants will begin immediately. The closing date for applications is February

An Equal Opportunity/Affirmative Action Employer. (NW106)A

#### HIGH ALTITUDE OBSERVATORY

Visitor Appointments at the High Altitude Observatory are available for new and established PhD's for up to one year periods to carry out research in solar physics, solar-terrestrial physics, and related subjects. Applicants should provide a curriculum vitae including education, work experience, publications, the names of three scientists familiar with their work, and a statement of their research plans.

Applications must be received by 15 January 1982, and they should be sent to: Visitor Committee, High Altitude Observatory, National Center for Atmospheric Research (NCAR), PO Box 3000, Boulder, Colorado 80307. NCAR is an Equal Opportunityy/Affirmative Action Employer

#### **BIOCHIMISTE/PHARMACOLOGUE** — **REGION PARISIENNE**

Un des principaux groupes pharmaceutiques français du secteur privé recherche un biochimiste expérimenté orienté vers la pharmacologie moléculaire pour un poste de haut niveau, avant une expérience d'au moins cinq ans dans l'industrie pharmaceutique, ou ayant dirigé une importante Unité de recherches à l'Université, de préférence dans le domaine cardiovasculaire, SNC ou sécrétion gastrique.

Ce poste conviendrait à un candidat pouvant prouver son expérience par une liste importante de publications.

Envoyer CV et liste des publications sous référence W502, c/o Nature, Macmillans Journals, 4 Little Essex Street, London WC2R 3LF.

Discrétion assurée.

(W502)

#### The Queen's University of Belfast

#### RESEARCH ASSISTANT Marine Biology Station, Portaferry

This NERC financed project tenable for three years will be concerned with a study of factors contributing to increases in phytoplankton productivity and biomass in oceanic shelf-break and frontal zones. An ability to undertake work at sea will be necessary.

Commencing salary £5,286 rising to £6,072 per annum with USS.

Further particulars may be obtained from Dr G Savidge, QUB Marine Biology Station, Portaferry, Co Down BT22 IPF, Northern Ireland. Applications, giving the names and addresses of two referees,

should be sent to the Personnel Officer, The Queen's University Officer, The Queen's University of Belfast BT7 1NN, Northern Ireland. Closing date: 14 December 1981 (Please quote Ref 81/N) (9957)A

#### PROFESSIONAL RESEARCH ASSISTANT IN CARBOHYDRATE CHEMISTRY

To participate in the purification and structural analysis of biologically interesting complex carbohydrates using modern instrumentation such as NMR, GC, GC-MS, LC and LC-MS. Applicants should have the equivalent of a BSc or MSc in Chemistry or Biochemistry. Starting salary (between \$12,000 and \$16,000) will depend on experience. The University of Colorado is an affirmative action/equal opportunity employer.

Applications should be sent to Michael McNeil or Peter Alber-sheim, Department of Chemistry, University of Colorado, Campus Box 215, Boulder, Colorado 80309, and should be received by December 31, (NIWOR9)A

#### A PROFESSORSHIP (C2)

will be available in the Department of Medical Microbiology at the Free University of Berlin. Preference will be given to a person with ample research experience in the field of T-cell dependent anti-infectious immunity. Obligations are, besides research, teaching and participation in the diagnostic bacteriological routine work, for the latter activity, no particular experience necessary.

For further information contact: Prof. Dr med. Helmut Hahn, Institute für Medizinische Mikrobiologie der Freien Universität Berlin Hindenburgdamm 27, D-1000 Berlin (W498)A 45. West Germany.

#### **IMMUNOLOGIST** FRED HUTCHINSON CANCER RESEARCH CENTER

The Fred Hutchinson Cancer Research Centre conducts a broad based program in basic biological sciences. The Center wishes to recruit a faculty scientist with an established record of accomplishment in basic immunology to join this program. Considerable space and resources are available. Interested individuals should submit curriculum vitae and suggested references by December 20, 1981 to:

Associate Director for Scientific Programs, Fred Hutchinson Cancer Research Center, 1124 Columbia Street, Seattle, WA 98104.

FHCRC is an Equal Opportunity/Affirmative Action employer (NW103)A

#### MLSO OR BASIC GRADE BIOCHEMIST

There is a vacancy for a Medical Laboratory Scientific Officer or a Basic Grade Biochemist to assist in routine Clinical Biochemistry Laboratory. The work is varied and may provide an opportunity to gain experience in some special techniques for estimating biogenic amine metabolism, for which the laboratory is a reference centre.

Applications with names of referees to Professor M.
Sandler, Queen Charlotte's Maternity Hospital, Goldhawk
Road, London W6. (9934)A

#### UNIVERSITY OF WESTERN ONTARIO Cancer Research Laboratory POSTDOCTORAL FELLOWS

Staff includes Drs. G. Chaconas, K. Ebisuzaki, E. Faust, D. Fujita and B. Milavetz. Areas of research include DNA replication, poly (ADP)ribose metabolism, tumour virology, control of mammalian cell cycle, and cloning of mammalian genes with particular reference to cancer. Submit curriculum vitae and letters of reference to Dr. David Denhardt, Cancer Research Laboratory, University of Western Ontario, London N6A 5B7 Canada. (NW102)A

JUNIOR Laboratory Scientific Officer required in Department of Microbiology for one year to assist in clinical research project on viruses in chronic arthritis. Previous experience in virology or cell culture an advantage. Salary in range £2,929 — £4,055, or £3,120 — £4,220, according to age and qualifications, plus £859 London Weighting. Apply in writing, stating age and giving details of qualifications and experience, to the Secretary, Guy's Hospital Medical School, London Bridge SE1 9RT, quoting Ref. MC4. (9967)A

## UNIVERSITY OF OXFORD

DEPARTMENT OF AGRICULTURAL AND FOREST SCIENCES RESEARCH ASSISTANT

Applications are invited for an ARC-funded post, to work on the physiology of disease resistance mechanisms in conifer roots, in collaboration with Dr R B Pearce. This post, which is tenable for three years, will commence on 1st February 1982 or as soon as possible thereafter. Salary range £5,285 to £8,925 pa.

Applicants should have research experience in plant pathology, plant biochemistry, or an allied field.

Applications, including a curriculum vitae and the names of two referees should be sent by 18th December 1981 to the Administrator, Department of Agricultural and Forest Sciences, Commonwealth Forestry Institute, South Parks Road, Oxford OX1 3RB from whom further particulars may be obtained. (9954)A

# CHEMISTRY University of Toronto SCARBOROUGH COLLEGE

A one year limited-term Assistant Professor appointment in Organic Chemistry or Physical Chemistry available July 1 or September 1, 1982. Doctorate required with expertise in Organic Chemistry or Physical Chemistry. Duties include undergraduate teaching and research.

Send curriculum vitae and names of three referees to: John E. Dove, Chairman, Physical Sciences Division, Scarborough College, 1265 Military Trail, West Hill, Ontario, Canada M1C 1A4. (NW115)A

# IMMUNOLOGY OF DIABETES

Applications are invited for the position of assistant or associate professor to work in the area of the aetiology of diabetes. The position, available on July 1, 1982, will carry an initial appointment of five years funded through *The Banting and Best Diabetes Centre, University of Toronto* at a competitive salary

Candidates should have a strong background in immunology and be interested in developing a strong research program in the areas of autoimmunity and/or immunogenetics related to diabetes. A colony of partially inbred (11 generations) spontaneously diabetic, BB Wistar Rats is available for research purposes.

The successful candidate will be expected to attract independent research grants and to spend at least 75% of his/her time carrying out an independent research program. Teaching obligations will be minimal.

Applicants should forward a curriculum vitae, an outline of Research Interests and the names of three references to Dr David H Maclennan, Professor and Chairman, Banting and Best Department of Medical Research, 112 College Street, University of Toronto, M5G 1L6, Toronto, Ontario. (NW112)A

#### QUEEN'S UNIVERSITY Kingston, Ontario

The Department of Biology invites applications for three positions. Successful applicants will be expected to teach in the undergraduate program and develop vigorous research and graduate education programs. Appointments will be effective September 1, 1982 and are expected to be at, but are not restricted to, the rank of Assistant Professor with salary commensurate with qualifications (floor — \$20,800). Equal opportunities exist for qualified male or female applicants. First consideration will be given to Canadian citizens or landed immigrants. All positions require a PhD degree and published evidence of excellent research ability.

#### **PLANT ECOLOGIST**

Tenure track position. Preference will be given to persons with active interests in population or community ecology of land plants. Research program will be expected to emphasize a quantitative experimental approach and the application of ecological and evolutionary theory to problems of plantecology. It is expected that the successful applicant will interact closely with the present faculty in population biology.

#### PLANT DEVELOPMENT

Tenure track position. Applicants must have expertise in plant cell and tissue culture, including plant regeneration and are expected to be able to interact closely with present faculty in plant physiology/development and recombinant DNA technology.

#### **CELL BIOLOGIST**

One year term appointment with the possibility of renewal. Applicants are expected to have research interests in animal cell biology, possibly including fine structure, and be able to interact closely with present faculty in cell biology. Successful applicant must be able to teach in a first-year cell structure and function course.

Application deadline is April 1, 1982 or until a suitable candidate is selected. Send applications, which should include a curriculum vitae, statement of future research interests and names and addresses of three referees, to Professor D. T. Canvin, Head, Department of Biology, Queen's University, Kingston, Ontario, Canada K7L 3N6.

(NW104)A

Agricultural Scientific Services, East Craigs, Edinburgh

Department of Agriculture and Fisheries for Scotland

# **Plant Pathologist**

. . . to lead a team assessing crop losses caused by diseases and pests (and possibly weed competition) and to investigate the cost/benefit of pesticide application to prevent such losses. The cost/benefit studies are expected to include a consideration of the effects of pesticide use on wildlife and the environment generally as well as the straightforward assessment of economic gains or losses.

Candidates, normally aged under 32, should have a good honours degree in a relevant discipline and at least 4 years' experience in agricultural plant pathology.

Appointment as Senior Scientific Officer £8,205 — £10,320 with starting salary according to qualifications and experience.

For further details and an application form (to be returned by 18 December 1981) write to Scottish Office, Personnel Division, E-PM(PTS)3, Room 208, 16 Waterloo Place, Edinburgh EH1 3DN, telephone 031-556-8400 extension 5088 or 4311. Please guote ref: SA/20/DLA.

#### **EMBO PRACTICAL COURSE**

#### Automated Chemical and Enzymic **Gene Synthesis**

Department of Biochemistry Technische Hochschule Darmstadt

#### MARCH 21st TO APRIL 3rd, 1982

The teaching staff will include:

J.H. van Boom (Leiden), M.H. Caruthers (Colorado), H.J. Fritz (Köln), M.J. Gait (Cambridge, UK), H.G. Gassen (Darmstadt), W. Hillen (Darmstadt), K. Itakura (City of Hope, LA), H. Kossel (Freiburg), H. Köster (Hamburg), K.E. Norris (Bagsvaerd), E. Ohtsuka (Osaka), H. Schott (Tübingen), H. Selinger (Ulm), O.C. Uhlenbeck (Urbana), E.L. Winnacker (München) and others.

The programme will consist of practical work, lectures and seminars on solid-phase chemical synthesis of oligodeoxynucleotides

- phosphotriester method as related to the phosphoroamidite procedure
- automated oligonucleotide synthesis
- oligonucleotides from DNA fragmentation enzymic ligation of oligonucleotides
- recombination of RNA
- survey of oligonucleotide separation and analysis
- ligation of synthetic genes (promotors) to plasmid vectors

A maximum of 15 students will be accepted. Applications should include a short curriculum vitae and a description of present research interets. The registration fee for the practical course is 200, DM, which does not include food and lodging. A small number of grants in aid to cover partially board and lodging expenses may be granted to participants who are unable to obtain funds from other sources.

The weekend MARCH 27/28th will be kept free from practical work to allow the participation in a WORKSHOP entitled

#### **Prospects of Automation in Gene Synthesis**

Informal application is sufficient for the workshop. The number of participants will be limited to 100. The registration fee is 60, DM.

#### THE CLOSING DATE FOR APPLICATIONS IS JANUARY 15th.

Those accepted will be notified not later than January 31st, 1982. Applications should be sent to Dr H.G. Gassen, T H Darmstadt, Institut für Organische Chemie und Biochemie, Petersenstrasse 22, D-6100 Darmstadt. Phone: 06151/163657, Telex: THD 419579 (W504) C

#### SEMINARS and SYMPOSIA

#### George Washington **University Spring** Symposium on Health Sciences (Washington, D.C. — May 18-21, 1982) Gene Expression '82

The conference will feature five sessions on gene structure, expression and gene transfer. Chromatin Structure: Gary Felsenfeld (NIH), A. Varshavsky (MIT), S. Elgin (St. Louis); Gene Structure: P. Leder (NIH), M. Wormington (Carnegie), Gene Structure: P. Leder (NIH), M. Wormington (Carnegie), A. Efstratiadis (Harvard), L. Kedes (Stanford), J. Seidman (NIH); Gene Expression: D. Hamer (NIH), G. Khoury (NIH), M. Wigler (CSH); Cell Free Systems: R. Roeder (St. Louis), P. Sharp (MIT), C. Parker (Caltech), B. Solnar-Webb (Johns Hopkins); Gene Transfer: F. Anderson (NIH), F. Ruddle (Yale), W. Salser (UCLA) and P. Hoppe (Maine).

There will be open registration for a limited number of participants including those who wish to make poster presentations. For further information write to:

#### STUDENTSHIPS

#### ST JOHN'S COLLEGE, Cambridge **RESEARCH STUDENTSHIPS**

The College now invites applications for a number of Research Studentships from men and women who are not already members of the College but who propose to register as PhD students at the University. The Studentships will normally be tenable for three years and of such value as will, in addition to the payment of fees, bring the student's total emoluments to £2,345 a year. Candidates should have gained or have a strong prospect of gaining a first-class honours degree or equivalent.

Further details and application forms can be obtained from the Senior Tutor, St John's College, Cambridge CB2 1TP. Completed applications must be received by 1 April 1982. (9956)F

#### A CALL FOR PAPERS

#### FOURTH INTERNATIONAL CONFERENCE ON PHYSICO-CHEMICAL HYDRODYNAMICS

June 14 through 17, 1982

#### The Roosevelt Hotel Madison Avenue and Forty-Fifth Street **New York City**

The Fourth International Conference on physico-chemical hydrodynamics organized by the New York Academy of Sciences and the City College of the City University of New York will concentrate on the following: Interface mechanics and multiphase systems; theory of turbulence and its applications; transport phenomena, chemical reacting systems and low reynolds number hydrodynamics; physico-chemical hydrodynamics of polymers and bio-systems; and physicochemical hydrodynamics in electrochemistry.

Prominent scientists from various countries will present the results of their recent investigations. Everyone interested in presenting a paper is invited to submit a title and a short abstract by February 15 and an extended abstract of two pages, which will be published in the Academy's annual series, by May 1 to one of the conference organizers: Benjamin Levich, Albert Einstein Professor of Science, or Robert Pfeffer, Chairman, both of the Department of Chemical Engineering at the City College of New York, New York, NY 10031.

#### UNIVERSITY OF ST ANDREWS

DEPARTMENT OF PHYSIOLOGY & PHARMACOLOGY

Applications are invited for a

#### RESEARCH **ASSISTANTSHIP**

in Neuropharmacology to study the actions of biologically active peptides. Some experience of electrophysiological techniques would be advantageous, but is not essential. The project is funded by the MRC and will run for three years. Starting salary within range £5,285 — £6,070 per annum, plus USS.

Applicants are asked to submit a curriculum vitae as soon as possible, along with the names of two referees, to the Secretary, Department of Physiology and Pharmacology, Bute Medical Buildings, St Andrews, Fife KY16 9TS. Further particulars may be obtained by 'phoning St Andrews (0334) 76161, ext. 7153 or 7138.

(9953)P

#### CAMBORNE SCHOOL OF MINES

MSc IN MINING GEOLOGY The Camborne School of Mines offers a one-year, full-time MSc course in Mining Geology, which is open to suitably qualified geologists.

A scholarship (covering fees and accommodation), tenable at the Camborne School of Mines, for this course 1982-3; is available from:

#### SELECTION TRUST LTD

Applicants for this scholarship should be geology graduates with good Honours degrees, and preference may be given to those with two or three years' experience.

In addition to this scholarship, limited financial support (for fees only) may be availabe from the School.

Further details including information on the scholarship may be obtained from the course Director, Camborne School of Mines, Pool, Redruth, Cornwall. Tel: 0209-714866. Telex 45315. Please quote reference no. 130 when replying. (9935)C

#### CONFERENCES and COURSES

#### **NATO Advances Studies Institute** FEBS Advanced Course 82/05

#### STRUCTURE AND FUNCTION OF PLANT GENOMES

Centro "Ettore Majorana" Erice, Sicily, September 1st-11th 1982

Main topics to be covered:

Structure organization and expression of nuclear genome Structure, organization and expression of chloroplast genome

Structure, organization and expression of chloroplast g
Structure, organization and expression of higher plants
mitochondrial genome
Biosynthesis of plant storage proteins
Genetic manipulation of higher plants

Genetic manipulation of higher plants

Nitrogen fixation

Molecular biology of host-pathogen interaction

Molecular Biology of plant viruses.

Further information may be obtained by writing to Dr Orsola TIBONI, Istituto di Microbiologia e Fisiologia Vegetable, P.O. Box 202, 27100 Pavia, Italy

No registration fee will charged. Board and lodging will be arranged by the School at a price of 450 U.S. dollars. The price includes transportation to and from the airport. A limited number of grants, to cover partially living expenses and travel costs are available.

Closing date for application March 15, 1982. Successful applicants will be notified by May 15th, 1982 and should provide a non-refundable deposit of 50 U.S. dollars (which will be deducted for the living (W509)C expenses).

#### **FELLOWSHIPS**

#### **EMBO**

**European Molecular Biology Organisation** 

#### LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY SPRING 1982 AWARDS

#### Next deadline: February 19, 1982

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country. Long term fellowships are awarded initially for one year, but subject to review of progress they are usually renewed for a second year. In cases of exceptional scientific merit renewal for a third year is possible. The followship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is February 19, 1982. Successful candidates will be notified of the their awards immediately after the meeting of the selection committee which is on April 30, 1982.

Application forms and further details may be obtained from Dr J Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F.R. Germany.

(W510)E

# IMPERIAL CANCER RESEARCH FUND RESEARCH FELLOWSHIP

Applications are invited for a three year postdoctoral appointment to clone mammalian DNA sequences specifying control regions, structural genes and transforming genes, and to test the expression and biological activity of the cloned sequences by the use of DNA transfection techniques and eukaryotic vector systems.

Salary range £8,787 to £10,837 (inclusive of London Allowance) with entry according to qualifications and experience.

For further information contact Dr M Fried (Tel. 01-242 0200 ext 297). Applications with curriculum vitae and the names of two referees should be sent to the Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2 England quoting reference no. 9/82. (9932)E

## THE UNIVERSITY OF MANCHESTER

DARESBURY LABORATORY

## EXAFS OF METALLOPROTEINS

Applications invited for one-year Post-Doctoral Research Fellowship with an interdisciplinary group of chemists, biochemists and physicists investigating the structure of metal sites in proteins by x-ray absorption spectroscopy using the Daresbury Synchrotron source. Persons of any relevant discipline are encouraged to apply. SERC-funded, commencing 1 January 1982. Salary range £6,880 — £7,700. Superannuation.

Applicants should write as soon as possible, sending a curriculum vitae and the names of three referees to Dr C D Garner, Department of Chemistry, The University, Manchester M13 9PL. (9961)E

#### **BRITISH DIABETIC ASSOCIATION**

Applications are invited for the following:

#### a) R.D. LAWRENCE RESEARCH FELLOWSHIP

Applications are invited from medical and science graduates of registrar or equivalent grade for this Fellowship in any field relevant to diabetes mellitus. The Fellowship is tenable in any approved institution in the United Kingdom for two years.

#### b) ELI LILLY FELLOWSHIP

Applications are invited from medical and science graduates of registrar or equivalent grade for this Fellowship in any field relevant to diabetes mellitus in children and young. The Fellowship is tenable in any approved institution in the United Kingdom for two years. Thursday 31st December 1981 is the closing date for both Fellowships and further details, together with the appropriate forms are obtainable from The Assistant Secretary, The British Diabetic Association, 10 Queen Anne Street, London W1M 0BD.

#### EMBO SENIOR FELLOWSHIPS

During 1982 the European Molecular Biology Organization will award a limited number of Senior Fellowships to exceptionally qualified molecular biologists from Europe and overseas wishing to spend a period of 6 or more months in laboratories in the countries listed below. These fellowships cannot however be awarded for exchanges between laboratories in the same country. To be eligible to compete for these fellowships a candidate must have at least 8 years post-doctoral research experience and have made distinguished contributions to molecular biology or related fields of science.

The fellowships will comprise a travel grant (tourist class air fare) for the fellow and his dependants and an appropriate stipend. Although initially awarded for not less than 6 months and no more than 12 months, the fellowships may, subject to review by the EMBO Fund Committee, be renewed for a further period.

Further information concerning the fellowships and stipends as well as application forms may be obtained from Dr. John Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 6900 Heidelberg, Federal Republic of Germany.

Completed applications recieved before February 19, 1982 will be reviewed by the Fund Committee on April 30, 1982 and any awards made can be activated immediately.

The Host laboratory must be one of the following countries; Austria, Belgium, Denmark, Finland, France, Federal Republic of Germany, Greece, Iceland, Ireland, Israel, Italy, Netherlands, Norway, Spain, Sweden, Switzerland, United Kingdom. (W511)E

#### UNIVERSITY OF OXFORD THE QUEEN'S COLLEGE BROWNE RESEARCH

#### BROWNE RESEARCH FELLOWSHIP

The College proposes to elect a man or woman to a Browne Research Fellowship in Botany or Zoology tenable for three years from 1 October 1982.

Further particulars may be obtained from the Provost, The Queen's College, Oxford OX1 4AW. (9929)E

### UNIVERSITY OF BIRMINGHAM

DEPARTMENT OF MICROBIOLOGY

#### RESEARCH FELLOWSHIP

Applications invited for this Post-Doctoral position for MRC-funded project on molecular basis for differential replication of virulent and attenuated influenza viruses at pyrexial temperatures. Candidates with experience in molecular virological techniques particularly welcome to apply.

Post tenable from 1 January, 1982 for 2 years 9 months. Salary on the Research Fellow 1A scale £6,070 — £10,575 plus superannuation. Maximum starting salary £8,105.

Further particulars from Assistant Registrar, (Sci & Eng), PO Box 363, Birmingham B15 2TT to whom applications (three copies) including full curriculum vitae and naming three referees should be sent by *Friday*, 18 December, 1981.

Please quote ref: NM6(r).

#### IMPERIAL CANCER RESEARCH FUND RESEARCH FELLOWSHIP

Applications are invited for a three year postdoctoral appointment to work with Dr Ian Kerr on the biochemistry of interferon action, the regulation of the interferon response and the role of the 2-5A system in relation to its wider possible significance in the control of cell growth and development. Experience with proteins and nucleic acids or genetic engineering techniques or membrane biochemistry and some familiarity with handling cells in tissue culture are desirable.

The position is available immediately and candidates should be free to take up the appointment by September 1982 at the latest. Salary range £8,787 to £10,837 (inclusive of London Allowance), with entry according to qualifications and experience.

For further information contact Dr Ian Kerr (tel. 01-242 0200 ext 337). Applications with full CV and the names and addresses of two referees should be sent to the Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2 by 1st Junuary 1982 quoting ref. 8/82. (9931)E

# Amersham offers 3'-end labelling kits which give you:

#### Convenience

All the reagents needed to label DNA in one kit.

#### **Flexibility**

Amersham's kits are available with or without cordycepin 5'-[ $\alpha$ -32P]triphosphate for maximum economy of label.

#### **Efficiency**

Labels all 3 types of 3'-end – protruding, blunt and recessed.

#### **Simplicity**

Few pipetting steps. Easy to handle volumes.

#### Quality

All batches of our kit are subject to rigorous quality control. A copy of the autoradiograph, obtained after labelling the standard DNA provided in a standard reaction, is supplied with each kit.

**PB.4025** Non-radioactive reagents +  $250\mu\text{Ci}$  cordycepin 5'-  $[\alpha^{-32}\text{P}]$  triphosphate, sufficient for 5 standard 3'-end labelling reactions.

**PB.4100** Non-radioactive reagents + 1mCi cordycepin 5'- $[\alpha$ - $^{32}P]$ triphosphate, sufficient for 20 ständard 3'-end labelling reactions.

**N.4005** Non-radioactive reagents only – sufficient for 5 standard 3"-end labelling reactions.

**N.4020** Non-radioactive reagents only – sufficient for 20 standard 3'-end labelling reactions.

Please call Amersham or your local representative for further details of our kits.

CHRISTMAS BOOKS SUPPLEMENT

# **ULTROPHOR**

Put wavy bands where they belong. Among yesterday's problems.

Banish wavy bands with Ultrophor, a unique new instrument designed exclusively for professional electrofocusers by LKB, electrofocusing pioneers since 1960.

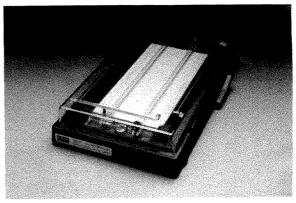

The ultracompact Ultrophor will cope with any analytical or preparative electrofocusing situation thanks to its radically new approach to electrode design, the construction of the highly efficient glass/aluminum cooling plate and the opportunity for atmospheric control.

The impressive list of bonuses include the flexibility of being able to run gels of any length up to 26 cm long or gels of any thickness, especially capillary-cast ultrathin gels, with less chance of wavy or skewed bands. The Ultrophor also has an unmatched capability to run high pH gels for sharp separations of alkaline samples as well as handle oxygensensitive or other labile samples.

Not only do you save valuable lab space with the compact Ultrophor but you save on time too because it's so fast and convenient to use and super-easy to clean. Like all LKB units, the new Ultrophor boasts a complete backup system and comprehensive technical support.

Contact your nearest LKB representative today for full information.

Ultrophor – the straight choice for professional electrofocusers.

# Polynucleotide Kinase From P-L... Since 1974, Used By More Researchers Than Any Other

More researchers have used and referenced P-L polynucleotide kinase (PNK) than any other. They prefer its high activity, proven nuclease-free quality, and economy.

P-L Biochemicals developed the first commercially available PNK in 1974. Since that time, it has gained such high acceptance that it has become the standard for functional purity. Most biochemists and molecular biologists acknowledge that P-L PNK is the best.

P-L polynucleotide kinase was assayed by the Richardson method using DNA substrate prepared according to the published procedure, along with PNK's from other commercial sources. The P-L PNK showed the highest activity at the lowest unit cost (P-L Analects Vol. 9, No. 4). Researchers have learned that because of this high level of activity and purity, they are getting more efficient end labeling at a better value with P-L PNK.

An example of the quality and useful-

ness of P-L PNK is shown in this photograph of an autoradiogram from a RNA sequencing experiment. E. coli 5S ribosomal RNA was 5'-end labeled with 32P-ATP in the presence of P-L Cat. No. 0734 PNK and repurified on a polyacrylamide gel. The figure shows the electrophoretic pattern obtained from a T nuclease digestion of the labeled 5S RNA as described in a recent P-L Analects article on RNA sequencing. The success of the labeling step with PNK is underscored by the fact that the gel pattern indicated G residues only at the correct positions - 13 from the 5'-end of 5S RNA.

#### P-L PNK Summary

Cat. No. 0734 polynucleotide kinase (2.7.1.78) (T<sub>4</sub>-infected *E. coli*)

TIBO SALOS OF THE OFFICE OF TH

Preparation: Solution of nearly homogeneous protein in 50% glycerol containing 0.02 M potassium phosphate, 0.025 M KCl, 0.01 M 2-mercaptoethanol, and 10-7 M ATP (pH 7.0).

Activity: Not less than 15,000 units per mg protein. One unit catalyzes the transfer of one nanomole phosphate to the 5'-OH end of a polynucleotide from  $(y^{-32}P)$ -ATP in 30 minutes at 37°C.

Contaminating enzymes: Trace or no detectable hydrolysis of supercoiled plasmid DNA, [14C]poly(U), or [14C]poly(dT). Specific contaminating assay data are provided in the certificate of analysis that accompanies each lot of enzyme.

Package sizes: 100 units (200 Richardson units); 500 units (1000 Richardson units).

# New surfaces for cell culture

Now you can choose the most suitable microcarrier for your culture

Cytodex microcarriers bring new opportunities to

- routine and experimental cell culture
- production of viruses, interferon and other cell products
- in vitro studies on differentiation and metabolism

Cytodex 1

The microcarrier proven to be effective for growing more than 100 different cell types.

Cytodex 2 Especially developed for better yields of viruses and cell products. Retains all the advantages of Cytodex 1 with the added benefit of new charged groups necessary for cell attachment localized only on the surface of the microcarriers.

Cytodex 3 The latest concept in microcarriers. The stable collagen surface gives improved attachment and yields of many cell types, especially those normally difficult to grow in culture. Enzyme digestion of the surface gives improved recovery and viability of harvested cells.

Make the most of your cell cultures. For more information on how Cytodex microcarriers give you new opportunities in cell culture

Pharmacia Fine Chemicals AB Box 175 S-751 04 Uppsala 1 Sweden

# Hybri-Dot

#### For low cost, time-saving hybridization to "dots" of target DNA and RNA

BRL has designed a 96 well manifold that simplifies scale-up of the sensitive "dot hybridization" procedure for detection of specific DNA and RNA sequences. In this procedure, as little as one picogram of a specific nucleic acid sequence, bound to nitrocellulose as a small spot, can be detected using  $^{32}\text{P-labeled probe}~(\sim 10^8\text{dpm/}\mu\text{g}).$  Dot hybridization has been used to detect viral DNA in lymphocytes and in serum.

The 3 mm diameter sample wells of the BRL® Hybri® Dot™ System are arranged to precisely match the array of a standard 96-well microtitration plate. This simplifies and accelerates procedures such as the large-scale screening of bacterial colonies for recombinant plasmids.

**BRL No. 1050MM** 

#### **Features**

#### 96-Well Design Compatible with "Microtitration" Plates

Conveniently adapts to protocols using 96-well plates. Avoids time consuming tube handling and labeling.

#### • 3 mm Diameter "Spot"

Readily detects picogram quantities of nucleic acids hybridized to low levels of radioactive probe for conservation of valuable reagents.

#### Pre-cut, Indexed Nitrocellulose Sheets

Each Hybri®Dot™ System includes ten sheets of pre-cut nitrocellulose. Notched corners assure accurate reference afterremoval from the system.

#### Easy-to-Assemble, Precision Design

Unique, precision milled surfaces assure a secure, fluid-tight seal without gaskets, Orings or special tools.

BRL welcomes all questions concerning the performance of the Hybri•Dot™ System. Ask for a BRL Technical Services Representative at (800) 638-4045. To place an order, contact Customer Services Department at (800) 638-8992.

# The fraction collector that turns science fiction into science

Just a few years ago no one would have believed that a fraction collector like SuperRac could exist. Most researchers were used to their constant-volume and constant-time collectors – with level-sensors at best.

Many were resigned to a compromise between resolution and the efficient use of collection vessels.

SuperRac will change all that.

To begin with, SuperRac has built-in slope detection. Unlike a simple level sensor, it cuts peaks at their true beginnings and ends. You can even collect unresolved peaks in well-resolved fractions . . . and you never need to worry about baseline drift.

SuperRac also diverts uninteresting eluate to a waste trough - via a valve -

so you use fewer test tubes.

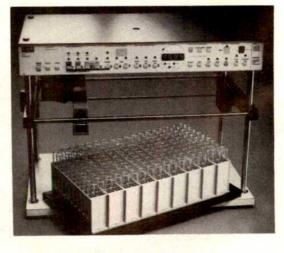

SuperRac's memory stores five different collection procedures that you can recall at the touch of a button. It has nine time windows allowing you to limit collection to interesting parts of your chromatogram.

SuperRac automatically compensates for asymmetric peaks and peak-width broadening during an isocratic elution. And it continues to run the pump for a specified time after a collection to clean and equilibrate the system.

Ask your local LKB distributor for more information on the new SuperRac. He'll give you several more reasons why we named it Super.

# Meeting heavy demands for lightwave transmission

The promise that emerging lightwave communications technology offered just a few short years ago is about to be fulfilled as telecommunications authorities the world over upgrade or expand their networks with optical fibre systems. And Philips technology has contributed much to this state-of-the-art.

For example, Philips originated and developed the plasma-activated chemical vapour deposition (PCVD) method of manufacturing high quality fibre possessing a refractive index profile closely approximating the theoretically desired parabolic form.

Unlike other CVD methods, PCVD employs a non-isothermal microwave plasma to stimulate low-temperature reaction of the gases SiCl<sub>4</sub>, GeCl<sub>4</sub> and O<sub>2</sub> within a tube of pure silica glass. The plasma reaction zone is produced by a microwave resonator that passes to-and-fro along the entire length of the tube, a very even and thin layer of oxides being deposited at each pass. In this way many hundreds of layers can be deposited to achieve a graded index fibre profile that

An enlargement of the etched surface of an optical graded index fibre (50µ core and 125µ cladding diameter).

Circle No.01 on Reader Enquiry Card.

very closely resembles the ideal parabola.

Exceptionally high bandwidth measurements are obtained on continuous production runs of these fibres, typically 850 MHz per kilometer at 850nm wavelength, with a lowest value of approximately 600 MHz.Km, and a top value of 1200-1300 MHz.Km.

Philips also achieved a major breakthrough in the complex PCVD manufacturing process by speeding up deposition of the layers without any loss in fibre quality. Instead of the standard deposition speed of 0.2

gramme/minute, new techniques enable speeds up to one gramme/minute to be reached, thus reducing the time taken to prepare silica glass preforms from 25 minutes to only five minutes per fibre-kilometer.

Increasing optical fibre quality at lower production costs is one of the many ways in which Philips technology is helping to meet the heavy demands for lightwave transmission. Here are some of the practical applications.

Overhead optical fibre cable now provides a cost-effective solution to the problems of television and FM radio reception in mountainous regions. A six-core NKF optical fibre cable system has been installed on a 2.8 kilometer pole-route to connect the villages of Aste and Beon, in the French Pyrenees, into the local CATV network. One of the first overhead optical fibre routes in the world, it provides the population of this remote area with FM audio reception and a choice of four colour television channels.

Circle No.02 on Reader Enquiry Card.

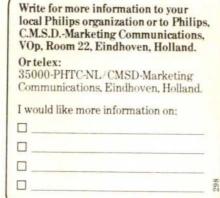

Lightwave telephone transmission. In addition to Philips all digital PRX/D exchanges, Saudi Arabia has ordered 140M/bits optical fibre systems to be integrated into the existing 2M/bits PCM networks in the Jeddah and Riyadh multi-exchange areas. Six-fibre cables, with a capacity of 1920 calls per fibre, will be used in the repeaterless routes, which total some 45 system kilometers. When completed it will be one of the first operational 140M/bits optical fibre transmission systems in the world. Circle No.12 on Reader Enquiry Card.

Optical fibre detection. The Philips SEM505 scanning electron microscope employs a unique optical fibre detection system within the specimen chamber. In the backscattered-electron mode, the system achieves the highest possible detection efficiency for highlighting topographic and/or atomic number contrast. When used for cathodoluminescence detection, a light-gathering lens focuses the signal on the fibre bundle. Light impulses from the detectors are routed to photomultiplier/preamplifier combinations via optical switches. The system provides an exceptionally high degree of flexibility as well as a very fast reaction time. This ensures that TVrate images can be obtained, even at low accelerating voltages, in all detection modes.

## The Hunters or the Hunted?

#### An Introduction to African Cave Taphonomy **CK BRAIN**

The author, director of the Transvaal Museum, Pretoria, devoted twelve years to the analysis and interpretation of nearly 20,000 hominid and animal fossils from the classic cave sites of Sterkfontein, Swartkraans, and Kromdraai. Brain asked "Who were the hunters and who the hunted? How did these bones enter the caves?" To answer these questions he was led into taphonomy, a new field for which there were virtually no guidelines at the time. Before the data could be interpreted, wideranging background studies — all reported here — dealing with many aspects of contemporary bone accumulation and preservation, by carnivores and humans, were undertaken in a variety of open-air and cave contexts.

Brain's research provides guidelines for taphonomic reconstruction that will help to ensure proper future excavation; it resolves specific controversies and generates new hypotheses regarding the behaviour, ecology, and evolution of South African australopithecines; and it provides the first comprehensive analysis of the Sterkfontein Valley cave fossil assemblage. 0-226-07089-1 365 pages, 226 figures, 121 tables, published December 1981, £24.50

#### The Life of Plants

E J H Corner

"An introduction to the world of plants which is novel without being eccentric." — *Nature*. First published in 1964, this book is available in paperback, December 1981. 0-226-11586-0, 330 pages, illustrated £5.95.

#### The Snouters

Form and Life of the Rhinogrades Harald Stumpke

Foreword by Gerolf Steiner, translated by Leigh Chadwick In 1941, a Swedish scientist encountered an entirely new order of mammals: the Rhinogrades or, more commonly, the snouters .... "This is a highly serious work, a masterpiece of evolutionary science fiction." — Stevan J Arnold, University of of Chicago 0-226-77895-9 118 pages, illustrated, £3.50, paperback.

# Tolerance but no quarter for creationism

Creation-science goes on trial next week in Arkansas. The issue is whether recent legislation establishes religion. It would be better that it should have been the freedom of teachers to say what they believe.

The trial which opens in Arkansas next Monday on the state's decision to legislate for equal time in the school curriculum for creationism and Darwinian evolution will not be as dramatic an occasion as the trial of the Tennessee biology teacher, Mr John Scopes, in 1928. Then the issue was whether a teacher could be prevented by the law from telling his students what Darwin said. (Technically, Scopes was found guilty and fined \$100, but his lawyer Clarence Darrow made such a monkey of the prosecution that the conviction was quashed by the United States Supreme Court.) Now the argument is about a much narrower constitutional issue. By requiring equal time for what is called "creation-science" with Darwinism, is the state of Arkansas violating the provision of the United States constitution that ensures the separation of religion and the state? The American Council for Civil Liberties, which is to its credit bringing suit against Arkansas, has chosen to argue that what is called creationscience, itself the creation of predominantly religious people, cannot be made a compulsory part of the curriculum in state schools without institutionalizing religion.

The issue is far from clear cut. Would it necessarily be a constitutional offence if a state board of education required schools to teach the early history of the Christian Church, plainly a matter of great cultural importance? Part of the weakness of the state's case is that under the "Balanced treatment for creation-science and evolution-science Act", rushed through the state legislature in March this year, the doctrine of equal time is vested in the law, and is not an administrative decision of the board of education. But the essential flaw, likely to fall outside the terms of reference of next week's trial, is the sheer folly implied by the term "creation-science".

Three separate questions arise — the status of Darwinism, the status of "creation-science" and the question of how the components of any school curriculum should be decided. The argument next week will be dominated by attempts to demonstrate that Darwinism and "creation-science" are equally valid explanations of the origin of the natural world. The state attorney-general's decision to call as a witness Professor Chandra Wickramasinghe, Sir Fred Hoyle's collaborator in the theory of life from outer space, is plainly meant to show that even among non-creationist scientists, Darwinism does not have the field to itself. The misfortune in the framework of next week's trial is that there will be no opportunity to challenge the assumption, not only in Arkansas, that state governments can sensibly intervene on specific matters of educational policy.

The status as a scientific theory of Darwinism was predictably well defined by Sir Andrew Huxley in his anniversary address to the Royal Society this week (see page 395). The supposed conflict on which the creationists have seized between the supposed gradualism of Darwinism and the observation that evolution may be episodic (chiefly due to S.J. Gould and N. Eldridge) is not a conflict at all. Gould will be saying just this at next week's trial. Neither is the problem of the "missing links" a problem. Darwinism has all the attributes of a mature and powerful scientific theory — newly discovered and apparently contradictory phenomena such as Mendelian inheritance have turned out to be confirmatory. And with the passage of time, the once perplexing question of how living things came to be the way they are has been particularized to a group of more tangible (if as yet

unanswered) questions, the regulation of embryogenesis and the evolutionary role of consciousness for example.

During the long correspondence on the role of the British Museum (Natural History) in the past year, much has been made of Sir Karl Popper's confusing remark that the theory of evolution is not falsifiable and must herefore be called "metaphysical". Like cladism in its own field, that is a useful way of classifying scientific theories, suggesting what kinds of tests may be considered compelling. But none of this is relevant to the function of the theory of evolution in scientific enquiry. What matters there is that the theory of evolution is found empirically - by biochemists as well as simple biologists - by planning investigations and designing experiments. To pretend that the theory carries no compelling conviction while problems remain unsolved is as ridiculous as it would be to hold that Newtonian mechanics (within its accepted field of validity) will remain unproven so long as the general three-body problem has not been solved.

Creationism, even when dignified as "creation-science", has a quite different status. Many working scientists, finding that it does not help in ordering thought or designing experiments, are tempted to dismiss it as rubbish. Individually, they are right to do so. Collectively, however, the scientific profession would be mistaken to seek to outlaw creationism. Many religious people find creationism a useful way of ordering their own non-scientific thoughts. Some religious Darwinists are also creationists, suggesting that the alternative ways of accounting for the natural world are orthogonal ways of ordering phenomena. But the scientific community's justifiable complaint against the resurgence of creationism in the past few years is that it is now called creation-science. For what will be given equal time in the Arkansas curriculum is not science at all in the sense of being a system for relating all phenomena in a certain domain to a single set of causes which are themselves susceptible to investigation. Toleration of this shoddy pretence has already gone too far, and in surprising places. (Nature's complaint, earlier this year, about evidence of creationist backsliding at the British Museum, is not sufficiently answered by Sir Andrew Huxley's assertion, earlier this week, that the signs were "so slight that most visitors do not even notice them".). The plain truth, which museum exhibitors and state legislators must recognize, is that creationism is not a part of science but an alternative to it.

However the trial next week is decided, the question will remain unresolved of how the curriculum in state schools should be decided. Improbably, the creationists may lose their case, but the right of state governments to specify the content of the school curriculum will be unchallenged. On paper, that right has a simple derivation. State schools are dependants of the state government, and those who teach in them are employees of their local governments. On the principle that public employees must be accountable to their paymasters for all aspects of their work, it is possible to argue that a state is well within its rights to require that teachers should teach whatever is required of them. So would a tobacco-growing state such as Virginia or North Carolina be allowed to instruct its teachers to play down the evidence for a link between smoking and lung cancer? States' rights apart, such a decision, however constitutional, would provoke an outcry that could not be gainsaid. And the American Council for Civil

Liberties would then be filing suit on the grounds of the First Amendment to the Constitution, that which assures free speech—in this case the teachers'.

Exactly the same argument applies to the disastrous legislation that the state of Arkansas has hung around its neck. (In the past few weeks, Mississippi has followed suit.) By requiring that biology teachers should in future teach "creation-science", it is requiring that honest people should tell what they consider to be lies in public. By doing so, Arkansas will undermine the professional integrity of a substantial part of the state's teaching staff and ultimately of the education system as a whole. Is it too much to hope that, when the trial is over — and however it is decided — Arkansas will have the wit to find some way of delegating the fine control of the school curriculum to those on whom the responsibility properly falls — the educationists employed for that purpose?

# What systems analysis?

Laxenburg has a new director but an uncertain future. It also needs a policy.

Not so long ago, in the early 1970s, governments throughout the world were being asked to subscribe to what was intended as a unique instrument of scientific collaboration between East and West — the creation of the International Institute of Applied Systems Analysis at Laxenburg near Vienna. How splendid, the prospectus read, that there should be a research institute (supported principally by the governments of the Soviet Union and the United States) dedicated to the application of objective methods of analysis to problems of contemporary importance throughout the world. Eventually, the misgivings of those who held that the prospectus put the cart before the horse — the objective of East-West collaboration before the definition of a tangible programme of research — were overcome. The institute came into being and has indeed been a place where people, mostly modellers, desk scientists and even social scientists from both sides of the European boundary, have worked alongside each other. The most conspicuous product of this effort has been the study on energy published earlier this year. Now, for two reasons, the institute is in for a sea-change.

The most immediate difficulty is financial. President Reagan's first budget in March deliberately required that the National Science Foundation should reduce spending on overseas activities in general. Nobody appears at the time to have appreciated that United States government support for the Vienna institute is laundered through the National Academy of Sciences until the academy pointed out that it would be unable to pay the subscription due this month. The United States Administration has now found the funds with which the academy can make the contribution legally required of it. Whether it will be able to remain a member in 1983 remains uncertain - and will not be known until the budget for 1983 is published next February. It is, however, a fair guess that if the United States if forced to withdraw, the Soviet Union (whose financial contribution is identical) will also do so. The Laxenburg institute, already somewhat shrunken, must live with uncertainty until the summer.

At first sight, this may seem the worst time for a new director to take charge at Laxenburg. That, however, is the opposite of the truth. If change of some kind is unavoidable, a new director may be an advantage. This is the spirit in which to regard the appointment of Professor C.S. Holling, an ecologist from the University of British Columbia, to Laxenburg with effect from 1 December. he may have to share some of the personal anxieties about the future that afflict the staff of the institute, but he is likely to be less strictly bound by past promises than his predecessors would have been. With a little luck, he may be able to devise a programme of research that can be tailored as the months go by to suit whatever budget becomes available in the year ahead.

But that kind of programme should that be? The trouble so far at Laxenburg is that the original scepticism about the institute has not been stilled by its achievements. The institute has laboured for

a decade and produced not so much a mouse as an elephant — a turgid account of familiar problems in the supply of and demand for energy that might have been illuminating if it could have been published several years earlier. Plainly that is a model for Dr Holling to avoid.

The question remains, however, of what is to be understood by the term "systems analysis" in the institute's title. Computer engineers have a simple answer, but the Laxenburg institute is intended as more than a computing centre. Originally, the phrase may have provided a seemingly innocuous unbrella beneath which people from different economic systems could work together. Now it may be necessary to acknowledge what has always been the truth — that the most useful problems for the institute to tackle are problems that impinge on economics and thus, because economics is the theory of social choice, on politics. What mechanisms should there be, for example, for sharing technological activity among industrialized states, the contemporary equivalent of Adam Smith's classical problem? How most efficiently can the supplies of natural gas to the industrialized world be used? And what can be said about the pattern of manufacturing industry and of world trade in the years ahead? With its unique constitution, the institute is well placed to capture international attention with attempts to answer such unspoken questions. The danger is that it will settle for yet another easy option, and devote itself to important but distant questions such as the problem of the accumulation of carbon dioxide in the atmosphere.

#### Yellow rain too soon

The United Nations commission on poisonous yellow rain in South-East Asia issued an inconclusive report. It would have been wiser not to comment.

The United Nations has done itself a power of harm by its appointment of a commission to investigate charges by the United States that the Soviet Union has been using biological weapons in South-East Asia and in Afghanistan. Last week, the commission (having been to South-East Asia but not to Afghanistan) said that it had been unable to reach a definite conclusion. This week, the commission (which would no doubt prefer to be released from its responsibilities) is likely to be asked by a formal resolution of the General Assembly to soldier on. Dr Kurt Waldheim, the Secretary-General of the United Nations, is no doubt hoping that by the time the next report on the subject appears, his own continued tenure of his important post will have been confirmed.

The tale of the yellow rain over South-East Asia is far too tortuous for anybody's comfort. The allegation that aerial sprays containing unusual amounts of mycotoxins have recently been sprayed over South-East Asia was first raised at the end of last year but was brought more firmly to public attention some weeks ago by the United States Secretary of State, Mr Alexander Haig, in a speech in Berlin. The subsequent tour of European capitals by a group of Mr Haig's choosing was notable partly for the anonymity of its members but chiefly for the vagueness of the extra evidence it was able to produce (see *Nature* 22 October, p.598). The group left those who heard what it had to say with the firm impression that it would have been happier if there had been more substance in what it said.

Unhappily, the passage of time is death for innuendo. Mr Haig charged that the Soviet Union sprayed mycotoxins from the genus Fusarium on innocent people. In was never self-evident why such a stratagem should be followed, even by supposedly malevolent people. Why not anthrax, for example? The classical disadvantage of biological weapons is, after all, well-known to be their slowness. Furthermore, even though further samples of soil containing mycotoxins have been produced, they may be there naturally, and it is premature to claim it as proof that these chemical agents were used. What the US government should do is to publish the data it has to hand in the scientific literature and let others judge for themselves what should be made of it. Jumping the gun is no way to world peace.

# Fusion chief resigns over budget cuts

# Mirror devices and tokamaks in conflict

Washington

The head of fusion research programmes in the United States Department of Energy (DoE) has resigned in protest at the way in which the Reagan Administration is proposing to allocate research funds between competing magnetic fusion projects.

His decision has apparently been provoked by the decision of the Office of Management and Budget (OMB), in drawing up the recommendation that President Reagan will present to Congress next January, to shift \$25 million from research into mirror devices being studied at the Lawrence Livermore National Laboratory in California to the Tokamak Fusion Test Reactor (TFTR) at the Princeton Plasma Physics Laboratory in New Jersey.

The most immediate impact, according to Dr Edwin Kintner, who has been head of DoE's research programme since 1977, and who last week submitted his resignation as associate director of the Office of Energy Research, will be to delay by about three years completion of the expanded Mirror Fusion Test Facility (known as MFTF-B) which many consider to be the principal competitor to the tokamak.

But the Administration's decision has broader implications, for it effectively undermines a strategy which has been developed by the department under Dr Kintner to diversify magnetic fusion research away from too great a dependence on the success of the Princeton work.

Support for such diversification was first endorsed by the Administration after a report prepared for DoE by an ad hoc committee under the chairmanship of Dr John S. Foster of TRW Inc. in 1978. This pointed out that although the Princeton tokamak programme was achieving impressive scientific results, many engineering problems remained before a viable power reactor could be built.

Concentrating purely on the tokamak, it said, constituted an "unnecessarily high risk". It suggested that the United States should "pursue fusion on a broad front", primarily into mirror devices but also into alternative designs.

After careful review, DoE selected two of these designs for increased support. One was the reversed field pinch, a combination of the tokamak and mirror designs. The other was the Elmo Bumpy Torus (EBT), under development at the Oak Ridge National Laboratory in Tennessee (see

Nature 1 May, p.3).

Mirror research was given further support by the successful development at the Lawrence Livermore Laboratory of tandem mirrors to plug the ends of a solenoid-containing plasma. As a result, it was decided last year to expand the first MFTF into a tandem mirror machine, MFTF-B, scheduled for completion in about four years' time and to perform at temperatures and confinement times comparable to the performance of the tokamak.

This strategy is now coming apart under the stringent budgetary pressures being applied by the Reagan Administration. The first potential casualty is likely to be the EBT "proof-of-principle" machine (EBT-P), proposed for construction by the Carter Administration under contract with McDonnell Douglas, but cut from DoE's budget by Mr Reagan in March. Although Congress has reinstated the money in an appropriations bill now sitting on the President's desk, which would provide \$14 million for EBT-P in the current year, it seems unlikely that he will sign it.

Overall, the 1982 budget for magnetic fusion does not look too bad. Although this was reduced in March from the \$506 million proposed by President Carter to \$456 million — partly by eliminating funds for a centre for magnetic fusion engineering which DoE had previously agreed to build under congressional pressure to move faster on magnetic fusion in general — the latter figure is still

sufficient to maintain a cost-of-living increase for the current financial year.

As with other federal agencies, however, it is the 1983 budget that is giving the greatest cause for concern in Washington as the Administration seeks further substantial cuts in public spending to reduce the federal deficit while increasing the military budget.

OMB's decision to shift support from the mirror programme to the TFTR "is a precedent-setting decision taken without an adequate hearing or technical discussion", Dr Kintner said last week, adding that he had been unable to persuade DoE to appeal and that it was going "to change the whole policy direction of magnetic fusion research for the future".

"For the first time we had a policy which made sense for fusion. It did not argue that we should start competing with other forms of nuclear energy by a definite date, but said we should first meet the short-term objective of knowing whether fusion is practical as an energy source. I worked for five years to create cooperative relationships and research strategies which made sense. That is all dead."

While the strategy of diversified research support has been pursued within DoE, however, it has come under some criticism from the nuclear industry and its congressional supporters who would like to see work proceed on an experimental tokamak reactor as quickly as possible and feel that the DoE strategy may have been overly cautious.

David Dickson

#### Cline stripped of research grants

Washington

In a move clearly intended to warn other scientists not to ignore restrictions laid down by the federal government, Dr Martin Cline of the University of California in Los Angeles (UCLA) has been stripped of one of four research grants he receives from the National Institutes of Health (NIH) because he carried out unauthorized experiments on human patients that involved the use of recombinant DNA techniques.

The incident first came to light last autumn, when it was revealed that, while treating patients in Israel and Italy suffering from  $\beta$ -thalassaemia, Dr Cline used bone marrow cells whose genetic material had been altered by recombinant DNA techniques, even though he had previously told both his university and the two hospitals involved that he would not do so.

Earlier this year, an investigatory committee established by NIH suggested various conditions that should be applied to future grants applications from Dr Cline, who had already resigned as chief of the division of haematology/oncology at UCLA, while retaining his university post as professor of oncology.

In the light of their conclusion that he had violated both federal regulations for the protection of human subjects and NIH guidelines for use of recombinant DNA technology, the members of the committee recommended — and the NIH director (then Dr Donald Fredrickson) accepted — that special prior approval be required for all future grant applications from him for research with either human subjects or recombinant DNA (*Nature* 4 June, p.369).

It was left to the advisory councils of various NIH institutes funding his research to decide what to do about existing grants. Two of them, the National Cancer Institute and the National Institute of Arthritis, Diabetes and Digestive and Kidney Diseases, have taken no direct action.

The advisory council to the National Heart, Lung and Blood Institute (NHLBI), however, decided on a harsher penalty than merely impressing conditions on future applications. It recommended that Dr Cline's current grant from the institute be terminated on 31 March 1982, the end of its first year of support.

The grant, a total of \$244,000, was to have been spread over a period of three years, and covered research into the effec-

tiveness of the insertion of human  $\beta$ -globin genes into mouse haematopoietic cells. A condition of this grant was that no work on human subjects should be involved.

In the case of the National Cancer Institute, two grants for which Dr Cline was the principal investigator were reviewed. The first, for research into normal and malignant haematopoietic cell replication, has been allowed to run until its expiry date at the end of next May, and a renewal application is now under consideration.

On the second grant, part of a four-year project in medical oncology with a total cost of \$3.3 million, the National Cancer Advisory Board has suggested that the grant be continued until 28 February 1982. A renewal grant application has already been submitted by UCLA, with Dr David Golde named to replace Dr Cline as the principal investigator.

Following the decision by Dr Tom Malone (acting director of NIH) to accept the recommendations of the three advisory boards, Dr Cline has pointed out that the termination of the NHLBI grant eliminates only about 20 per cent of his research support. He has also said that he has not decided whether or not to appeal against the decision. In a letter to NIH written in September, however, Dr Cline strongly criticizes the 14-month delay by the UCLA Human Subject Protection Committee in giving a definitive response to his request for permission to carry out experiments.

One sanction recommended by the NHLBI advisory council which was not endorsed by NIH was that Dr Cline be asked to provide assurances that he will not engage in human experimentation involving recombinant DNA for a three-year period. A memorandum from NIH associate director of extramural research, Dr William Raub, says that he does not believe it appropriate for NIH to impose such a sanction, "nor do I believe we have authority to do so". David Dickson

#### ARC biotechnology

#### **Cottage industry?**

The pips may squeak in British research, but biotechnology forges on. The UK Agricultural Research Council (ARC), whose budget shrank 3 per cent in real terms between 1979–80 and 1980–81, has actually been able to announce the setting up of a new research centre. Admittedly, it is in a portable home (a Portakabin), but it will house twelve researchers and provide a focus for ARC work on monoclonal antibodies.

Costing around £100,000 for the Portakabin and equipment, and £100,000 a year to run when it gets going in April next year, the centre will have two resident researchers, four technical staff, and — on average — six visitors from other ARC laboratories.

The goal is to produce a centre of expertise in the handling and creation of

hybridomas — which some ARC virologists have found to be tricky things to culture. The resident researchers at the new centre will work on their own projects (for example, suggest ARC officials, on creating hybridomas of cow, pig and sheep cell lines) and assist visitors with their own problems.

The first applications will be to the creation of specific antibodies to viral strains, such as the varieties of calf enteritis virus, to help research and — perhaps — create vaccines where these would be commercially useful. To this end the unit will also have production facilities large enough to conduct commercial trials.

Who will profit from this ARC commercialism, however, is a moot point. By law the council must pass patent rights to the National Research Development Corporation, now part of the British Technology Group which includes the National Enterprise Board. Unlike the Medical Research Council, ARC has no direct agreement with Celltech, the company created by the National Enterprise Board a year ago to exploit biotechnical developments in British research establishments and universities (and to pursue its own research); but, says Celltech, it would expect the new British Technology Group to consider them as potential developers of any ARC product. The British Technology Group, however, would be free to approach any company it wished — and that might be a new British Technology Group company specializing in agriculture.

ARC recently suggested that the British Technology Group should set up a kind of agricultural parallel to Celltech — in which, no doubt, the ARC would like to have the same exclusive rights and potential earnings as the Medical Research Council has in Celltech — and this idea is still being considered. The British Technology Group will not reveal what stage negotiations have reached, but the ARC do not seem particularly optimistic.

Celltech itself is certainly interested in veterinary applications of hybridomas, but the company does not want to be thought of as specializing only in monoclonal antibodies. Its first and so far only product is a monoclonal antibody against interferon, but Celltech's research and development is now evenly divided between monoclonals and recombinant DNA. Celltech also sees no immediate likelihood of involving itself in the genetic manipulation of plants, unlike the ARC, which has the area very much in mind.

Meanwhile ARC was last week still awaiting official confirmation of the European Council of Ministers agreement three weeks ago to go ahead with the European Commission's biotechnology research programme, which will specialize in agricultural applications. ARC has been closely involved with the definition of the programme, and might hope to win up to £100,000 a year in grants to supplement its

own £1 million annual spending in biotechnology — but only if it has the chance to appoint a strong scientific team to the Advisory Committee on Programme Management. This Brussels committee will ultimately examine research proposals within the programme and — by advising the Commission — effectively hand out the cash. Unfortunately ARC is at a far remove from the Department of Industry, which is in touch with Brussels on this matter, and there are fears that the council may not be approached in time for Britain to get strong representation on the committee.

Robert Walgate

#### Soviet universities

#### Research needed

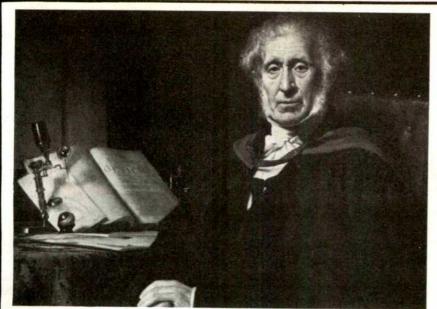

The Soviet Union must invest more in university science, according to Academician Ivan F. Obraztsov, Minister of Higher and Secondary Specialized Education of the Russian Republic. Writing in *Pravda*, he claimed that unless academic research is given priority, it will be difficult to train "good cadres" in the new directions needed for the Soviet economy to develop.

Obraztsov said that Soviet universities and higher educational institutions at present receive no capital funds specifically earmarked for science, although they carry out research worth more than 1,200 million roubles each year. Funds for scientific equipment and research materials are not forthcoming, and computers and similar sophisticated equipment appear far later in the universities than in institutes and laboratories run by specialized ministries.

The lack of funds seems to be especially serious in the engineering faculties. Although Soviet industry is committed to a policy of extensive automation, which is made more urgent by the Soviet Union's falling birth rate, the training of future engineers needs to undergo a "major restructuring". Obraztsov implied that means of familiarizing students with automated design systems, control systems, production lines and manmachine complexes simply do not exist.

The emphasis on engineers reflects a trend in the Soviet press. After a long "press debate" last year on why Soviet public opinion gives more prestige to the pure than to the applied sciences, the weekly *Literaturnaya Gazeta* last month published a round table discussion on the role, status and career prospects of Soviet engineers.

One complaint was that since 1948, engineers' salaries had risen by an average of 20 per cent in real terms, while those of "ordinary" workers had doubled. The participants also noted that young people seem reluctant to apply to engineering colleges. Many of the most prestigious higher technical schools, such as the Leningrad Mining Institute, no longer set competitive entrance examinations, while

The bicentenary of the birth of the Victorian scientist David Brewster was celebrated last week in a one-day symposium held at the Royal Scottish Museum in Edinburgh. Brewster's main claim to fame was his invention of the kaleidoscope, but he also made important contributions to work on the polarization of light. He later became Principal of the Universities of both St Andrews and Edinburgh, and was a major force in the establishment of the British Association for the Advancement of Science.

in a certain "fashionable" mathematics and mechanics faculty, the ratio of applicants to places was only 1.2 compared with 19.0 in a similar trade institute.

The impression that applied projects now take precedence was reinforced by last month's award of state prizes for science and technology. The projects honoured included work on urban water supplies from underground sources, the enrichment of desert pastures, bone transplants for diseases of the jaw and the future development of the fuel and mineral deposits of the Kansk-Achinsk basin. Even an apparently theoretical study of high temperature plasma was, according to Professor Nikolai Arzhanikov, the secretary of the awarding committee, "a major contribution" to the development of thermonuclear power.

The yearly stocktaking of Soviet life and progress which follows the Revolution Day parade included extensive press discussions of how to accelerate the implementation of research results in Soviet industry. Dr Boris Paton, president of the Ukrainian Academy of Sciences, suggested that the concept of "implementation" might profitably be deemphasized and the stress placed on "cooperation" between science and industry. The distinction is not trivial; enterprises which have an active role in developing new technologies, rather than simply "implementing" the results produced by some research institute, will be eligible to share in major Soviet prizes.

Whatever the form of the link between science and industry, however, it ultimately depends on an appropriate supply of scientists and technologists. During the past decade, science planners have concentrated on linking universities

and technical institutes into regional "science centres" whose research, it has been urged, should serve the needs of local industry. Obraztsov's complaints of the plight of universities suggests that too little attention has been paid to their major function as teaching and training establishments.

Vera Rich

#### Clean air legislation

#### Forces massing

Washington

Indecision within the Reagan Administration about how to reform the Clean Air Act is playing directly into the hands of environmentalist groups and their congressional supporters who feel that the act should be strengthened rather than weakened. It is also upsetting industry groups who had looked to the new Administration to reduce the burden of environmental and health regulations.

The current law was passed in 1970, and must be renewed by the Senate before the end of the year. The debate on revising the law is regarded as the first major test of President Reagan's determination to pursue his election promises of regulatory reform.

Even some members of the Carter Administration have argued the need for significant changes in the act. Last week the Brookings Institution in Washington published a paper by economist Lester B. Lave and Dr Gilbert Omenn, previously associate director for health sciences in the Office of Science and Technology Policy, which is sharply critical of current air quality legislation.

Claiming that the main reason the

nation's air has become cleaner in recent years has been the switch to cleaner energy-producing fuels, Dr Lave and Dr Omenn propose that the act should consider individual differences in susceptibility, as well as the availability of personal preventative health measures, when determining the acceptable "remaining risk" resulting from the various levels of proposed controls.

Industry itself is pushing for even greater changes. Public utilities, for example, are strongly resisting efforts to write into the act significant extra controls on emissions from power stations aimed at reducing the problems of so-called "acid rain" formed when sulphur dioxide reacts with atmospheric moisture.

How much is eventually changed, however, depends largely on the results of debates within the Senate Environment and Public Works Committee. And so far the lack of a clear battle plan from the Administration has left the initiative with those fighting to maintain the status quo.

The level of permissible emissions from motor vehicles has been one of the most contentious parts of the 1970 legislation. At the time, Congress set tight numerical limits on automobile and other vehicle emissions, with a strict timetable for their implementation, although under pressure from the automobile industry the deadlines have been gradually put back.

In their report for the Brookings Institution, Dr Lave and Dr Omenn argue that Congress should not be involved in setting detailed regulations for motor vehicle emissions because of the unnecessary rigidity that results. Instead, they say, Congress should delegate more, although still retaining the oversight role.

The Senate committee does not agree. For example, Environmental Protection Agency (EPA) assistant administrator Kathleen Bennett told the committee that, because of the expense involved, the Administration proposed to lower from 90 to 60 per cent the reduction in truck hydrocarbon and carbon monoxide emission required by 1984. But Senator Gary Hart replied that the figure of 60 per cent had been "plucked from the air" and argued that EPA should not be making economic decisions on public health issues.

Within the Administration, much of the blame for the current disarray in EPA's strategy is being placed on Administrator Mrs Ann Gorsuch, who announced in August that she would not be seeking major changes in the act, but was rather pushing for the inclusion of several basic principles on which future regulation should be based (Nature 13 August, p. 574). The result has been serious concern in several industries that the Administration is failing to fulfil its election promises. At the same time there is relief among Republican congressmen who already feel the worsening economic situation is jeopardizing their chances of re-election next David Dickson

#### Commercial rocketry

#### One for Ariane

Ariane, the European satellite launcher, has at last won a commercial place in the United States market. Last week, Arianespace, the French-based company which manages commercial exploitation of the European rocket, signed a firm \$50 million contract with the US General Telephone & Electronics (GTE) Satellite Corporation to launch two telecommunications satellites in 1984. The order, the first that Arianespace has won from an American customer, seems to confirm at least some of the fears of US space officials that Ariane could take business from the National Aeronautics and Space Administration, which until now has enjoyed a virtual monopoly outside the Eastern bloc for launching heavy satellites.

Ariane's chief attraction for US customers, who enjoy a 25 per cent discount, is its relatively low cost. At about \$25-\$30 million per satellite, an Ariane launch is 15-20 per cent less than a launch on a Thor-Delta rocket. Delays and uncertainties over the space shuttle have also made Ariane more competitive. Arianespace is optimistic that last week's deal will be followed by others.

Arianespace officials seem pleased with their own marketing efforts and those of the Grumman Corporation, their US agents. Twenty-one satellites from twelve customers, mainly European, have so far been committed for launch on sixteen Ariane flights. Three firm contracts, including that with the GTE Satellite Corporation, have been signed and sealed

since the third successful Ariane test flight last July. In addition, ten potential customers hold reservations for launching sixteen satellites on nine Ariane flights.

The order books are as healthy as can be expected after only three out of four test flights, according to Arianespace. Their future health, however, will depend on the fortunes of the fourth test flight scheduled for 18 December.

Judy Redfearn

#### European cooperation

#### **COST** in limbo

Brussels

The celebrations last week marking the tenth anniversary of COST, an organization pursuing "European Cooperation in the Field of Scientific and Technical Research", were appropriately low-key. Indeed, the role of COST itself has become so unobtrusive that its officials fear that its future is endangered by widespread ignorance of its purpose and even of its existence.

The chairman of the COST Senior Officials Committee, Johan Martin-Löf, speaking to the small group of senior officials and diplomats which had gathered to celebrate the anniversary, did his best to emphasize COST's solid achievements: that 35 different research projects had begun in the past decade, ten of them had been completed, and that this had involved ten EEC member states and nine other West European countries, all for a small extra outlay.

Part of COST's problem is that it is not a conventional international organization but a club which invites member countries to share the results of usually public

research. Once a project has been agreed by the intricate committee structure, individual member countries select the aspects they wish to work on and by financing only its own share of a project, each participant country has the right to the results of the entire research effort.

COST's vague status has complicated the administrative problems of coordinating the research programmes of 19 countries. A small secretariat in Brussels is its only direct physical manifestation. A major obstacle for those taking part in COST projects is the financing of travel. And Martin-Löf admits that "the time it takes to handle even relatively simple matters is often excessive". A further problem is the lack of money for the administration of projects once launched.

Suggestions for new projects have to come from the member states themselves and the most dynamic field for new projects seems to be in telecommunications, transport and materials science. Last week, a memorandum of understanding was signed for the COST project on high-temperature materials for power plants.

Jasper Becker

#### Asian ecology

#### Loss of balance

Bangalore

The increasing demand for wood for fuel in Nepal and Thailand is threatening the ecological balance of a large part of South Asia. In Nepal, deforestation is so rapid that it has been estimated that the country will be without forest by the year 2000.

The lack of tree cover is already causing two major problems. First, the once fertile valley lands are losing their ability to assimilate rainwater, causing a decline in vegetation, fast-spreading aridity and bird migration. Second, an estimated 240 million cubic metres of top soil is being carried into streams and rivers flowing into India and Bangladesh.

It was not until 1976 that the Nepalese government acknowledged the magnitude of the danger. It has now launched a 400 million rupee project, to be financed by the International Development Agency and other organizations, which aims to convert nearly 50,000 hectares of land into community forests over the next five years to meet the growing need for firewood.

In Thailand the government is also undertaking a replanting scheme concentrating on high-yielding rubber trees. The old unproductive rubber trees are to be used as construction materials in a plan which should, says the Thai Agriculture Ministry, bring in around \$60 million. Trials have shown that trees can be sprayed with chemicals and conserved at plantation sites for up to two years — at present more than 80 per cent of old rubber trees are felled and burned in a haphazard manner. Agricultural scientists have also examined the possibility of using the old trees for B. Radhakrishna Rao pulp.

#### Harsh sentence for Paritskii

A Khar'kov court has sentenced Aleksandr Paritskii, a 43-year-old specialist in electronics, to three years in a labour camp. The sentence was the maximum possible for his formal offence — disseminating anti-Soviet propaganda. Its severity may be due to one of Paritskii's activities which was not mentioned in the formal charge — the organization of a weekend "university" for young refusniks and the children of Jewish activists.

Exclusion from higher education is one of the regular sanctions imposed on those Jews caught in the limbo between applying for an emigration visa and actually being allowed to leave the country, and a fortiori on those formally refused permission to leave. Although since 1973 an increasing number of unofficial seminars have been organized for refusniks excluded from employment in the academic professions, until recently nothing formal had been done at undergraduate level.

In autumn 1980, however, Paritskii and a handful of fellow activists in

Khar'kov founded their "refusniks' university" with 25 students. Structured courses were held every weekend, throughout the academic year. Mounting harassment of Paritskii, followed by his arrest, has made it impossible for the university to reconvene this year.

The absence of the university from Paritskii's charge-sheet is interesting. Paritskii's colleagues from the "university" were not even called in for interrogation in connection with his trial. This may well mean that the authorities fear that an open attack on the "university" may simply result in a similar initiative springing up elsewhere and hope that with Paritskii gone, the "university" will simply disappear. Certainly the authorities seem to be interested in undermining his academic reputation. Earlier this year, he was one of three refusnik scientists who, in a move unprecedented in the Soviet Union, were deprived of their "Candidate" (PhD) degrees because of their political views. Vera Rich

#### Theory of evolution

#### Huxley speaks up

Sir Andrew Huxley, his grandfather's grandson, startled the Anniversary Meeting of the Royal Society this week with a stout defence of the theory of evolution. Traditionally, presidents have used these occasions for making gentle complaints about the British government's handling of science and education. But Huxley, starting with Sir Edmund Leach's statement at the British Association meeting this year (see *Nature 3* September, p.19) that many of Wilberforce's nineteenth century criticisms of Darwin were now accepted, said "here is a Huxley answering the challenge".

The correspondence in the past twelve months about cladistics and the British Museum (Natural History) still seems to rankle. In defence of cladistics, Huxley said that even the insistence of "transformed cladists" that taxonomic classifications should be made without reference to "necessarily conjectural" ideas about evolutionary processes and

#### University problems

Among the points in the secular part of Sir Andrew Huxley's anniversary address on Monday were the following:

- The dual support system for academic research, "a shadow of what it used to be", is in danger of being totally obliterated.
- Although the British government had agreed in its expenditure white paper in March to protect basic research, research councils are having to spend more on making good deficiencies of university budgets and are thus less able to support new research projects.
- There is a danger that universities will respond to this summer's budget cuts by further reductions of support for their own research.
- If a university "shows that it is moving in the right direction", the British government should be prepared to reduce the speed or the severity with which cuts are required.
- On the increased fees for overseas students, "I wish to add my voice to the many who have expressed dismay at this drop in our contribution to development, and at the loss of goodwill towards Britain that this policy will entail in the long run".

The society's annual report, also published this week, records that its own subvention from the British government increased to £4.2 million in the year just ended, from £3.7 million the previous year. General administration cost £564,000 — the rest was spent on support for people, international exchanges, grants for research and on international subscriptions.

selective pressures "is in no sense a denial of evolution".

Huxley said that his reaction to the correspondence in *Nature* had been to wonder whether he should "take up the cudgels on Darwin's behalf", but that he had been "mollified" by a "very sensible editorial article" in *Nature* (30 July, p.395). His concern now was to counter the "ripples [which] continue to spread".

In passing, Huxley said that the calculations of Hoyle and Wickramasinghe (see Nature 12 November, p.105) suggesting that there could not have been enough time since the origin of the Universe for life to have evolved could be "dismissed quickly". He said that the characteristic large number used by the authors (1040,000) represents the chance that 2.000 enzyme molecules would be formed simultaneously "on a single specified occasion". "Since we know neither the nature of the hypothetical self-replicating system nor the composition of the primaeval soup", the conclusion is, however, "wildly uncertain".

It is unlikely that Hoyle and Wickramasinghe will accept their dismissal on these grounds. Their arguments are based on the "information content" of the evolved genome, and on estimates of the rate at which information content might plausibly accumulate.

Huxley in defence of evolution

On the doctrine of Gould and Eldridge of punctuated equilibria, Huxley said that the debate lies within the Darwinian framework but that its authors have exaggerated the suddenness with which new stable species emerge. In any case, he said, Darwin's own guess that it would take ten or a hundred thousand generations for two "well-formed" species to emerge from a single species is not inconsistent with the doctrine of punctuated equilibria, while later editions of The Origin of Species, like the writings of neo-Darwinians such as G.G. Simpson, contain statements which are "exactly equivalent" to punctuated equilibria. In the circumstances, Huxley said, he could not understand how

#### Rhesus monkeys die

The University of Birmingham is being forced by financial and legal circumstances to kill most of its once thriving monkey colony.

Unable to raise the £250,000 needed to bring its monkey housing up to present safety standards, the university has for the past two years been exploring the possibility of dispersing all the animals elsewhere. Although there is no shortage of willing recipients, the university has finally decided that the probable legal risks in dispersing its adult monkeys are too great to delay any longer what they see as the almost inevitable slaughter of the animals.

The legal difficulties arise because almost all the adult rhesus monkeys have been used for experimental purposes under Certificate B of the Prevention of Cruelty to Animals Act which demands that animals be killed at the end of an experiment. Many experiments on the Birmingham monkeys were in midstream when they were stopped by the university pending modernization of the housing.

Since the experiments were interrupted rather than finished, it has been argued that the monkeys could be transferred elsewhere and experimentation continued. But the university, in consultation with the Home Office, has decided that it would be too risky to test that interpretation of the law.

Peter Newmark

punctuated equilibria could be regarded as contrary either to Darwin's own ideas or to those of neo-Darwinism.

On Sir Edmund Leach's echo of Wilberforce's complaint that the fossil record lacks evidence of the "missing links" between major stable groups of species, Huxley replied with a list of "missing links" whose discovery "has gone on at an increasing rate since before the publication of *The Origin of Species* to the present day", such as *Archaeopteryx* (1861), the fossil horses and hominids more ancient than the Neanderthals.

Huxley went on to dismiss other complaints made by Wilberforce and Owen a century ago, chiding anti-evolutionists for overlooking the "positive indications" from biochemistry, which have demonstrated the "ubiquity of the main metabolic pathways" and of Mendelian inheritance — "precisely what Darwin needed".

Likening the present status of evolution to that of biochemistry fifty years ago, Huxley listed the remaining "gaps" that seem to him important — the absence of evidence for the origin of the major groups of animals in the Palaeozoic, the inheritance of interspecific sterility, the role of genetic drift, the origin of life and the existence of consciousness — "too often swept under the carpet".

## RRESPINDENCE

#### Hoyle on life

SIR — Surely there is some mistake in your summary of Hoyle's contention that the Universe has not been here long enough to permit the evolution of life forms of the complexity found on this planet (*Nature* 12 November, p.105).

It is true that the probability of chance assembly of the system of genes upon which our life system depends is very low. However, it is not this particular probability which is relevant, but rather the result of multiplying this admittedly small number with the very large number representing the total number of gene systems which could also be the basis for complex life forms.

Any particular gene possesses its enzymatic properties as the result of its configuration in some quite small part of its total chain length. Although the chance of random assembly of the total chain, specified at every point, is small, the chance of assembly of a gene specified over a small fraction of its length is obviously much larger.

If you modify your account of Hoyle's arguments along these lines, I suggest you will conclude that we are all here after all.

#### **Postdocs in Canada**

SIR - I would like to pass on some news that I have just obtained with regard to the status of foreign postdoctoral fellows working in Canada. The Canadian Immigration Regulations require that before a foreigner can be offered employment, the position must be advertised through Canada Employment Centres, and suitably qualified nationals must be given preference. This regulation does not apply to postdoctoral fellows, but Canadian officials both in London, England and in Toronto assured my wife and myself that it did apply to their spouses. When we came to Canada last year my wife was unable to find a job, and since postdocs in biological sciences are not well paid (see Nature 11 June and 8 October), it became necessary for my wife to return to England to work.

This seemed an unfair system, so I brought it to the attention of Lloyd Axworthy, the Canadian Minister of Employment and Immigration. I have received a reply from him to the effect that since such restrictions do not apply to Canadian postdocs going to work in Britain, Canada is prepared, in this case, to reciprocate. He is instructing all Canadian immigration officials that this is now the case. So in the future, married postdocs will be able to move between both countries without facing financial hardship. However, it is implied that this relaxation does not apply to individuals from countries which do not already show hospitality to Canadians. I am impressed by the fact that the experience of an individual can successfully modify governmental regulations, but surely it is opportune, and for the mutual benefit of all concerned, for all countries which wish to foster academic exchange to take steps to relax immigration rules for the families of postdoctoral fellows. DYLAN EDWARDS

The University of Western Ontario, London, Canada

#### **Open relations**

SIR — Your article about the agreement between this hospital and the international chemical company Hoechst AG (Nature 5 November, p.5) states that the Government Accounting Office forced open the contract heretofore kept from Congressman Albert Gore. In fact, Massachusetts General Hospital gave the document to Congressman Gore on 21 July 1981.

What we did in October was to make the contract available to the general public from whom we have had a number of requests. In fact, we know of no other instance in which such a contract has been made available to the public. We have taken this course because we are presenting the agreement to our external Scientific Advisory Committee this month. The committee's topic, scheduled many months ago, is scientific relations with industry.

JOSEPH B. MARTIN Massachusetts General Hospital, Boston, Massachusetts, USA.

#### Life out there

SIR - It was interesting to read in iuxtaposition Dr Zuckerman's review of the extraterrestrial issue and Professor O'Neill's review of Rood and Trefill's new book on the same subject (Nature 5 November, pp.10, 25). One is struck again by the fascination - not to say fixation - that earlier and "young revolutionary" students of this issue have had with technology as an index of "advanced" civilization. The idea that other planets may have chosen to focus on spiritual rather than technical development dates back to at least the eighteenth century polymath Swedenborg. As is often noted nowadays, the validity of technology - rather than, say, spirituality as an index of cultural achievement is less than clear even for our own globe. It seems premature to disregard the Drake (or Green Bank) equation simply due to lack of verification of its technology/colonization components. What is called for instead, perhaps, is greater conceptual bandwidth in its KURT SIMONS formulation. Wills Eye Hospital, Philadelphia, Pennsylvania, USA

#### Leave links open

Sir — Dorothy Hirsch, Executive Director of the Committee for Concerned Scientists, ended her eloquent letter (Nature 13 August. p.578) about the plight of Soviet scientists with the charge to us that "We cannot afford to become hardened to the plight of oppressed colleagues who have much to contribute to a vital international science". Time (28 September) reports that exiled Soviet writers, despite enormous grievances against the Soviet government, have pleaded that free world publishers should not boycott the Moscow International Book Fair which means so much to the ordinary Russian citizen as well as the Russian literati. I have just returned from an international medical/scientific congress in Moscow, and wish to make a similar appeal to Western scientific groups resolved to boycott all scientific interchanges hosted by the Soviets.

At that congress I concluded my scientific presentation with a slide listing a dozen of the Soviet scientists sentenced to "internal exile"

(imprisonment) for their dissident views, and stated simply that my presentation was dedicated to "these fellow scientists in the sincere hope thay they may be free again some day soon to join with their colleagues from other nations in open scientific interchanges such as this one". It is still tearful for me to recall the response of the stony-faced Russian scientists in the audience to that statement. Almost in unison, they lowered their eyes, nodded very slightly, and a whispered chorus of "Da! Da!" ("Yes! Yes! Yes! Yes!") filled that Moscow meeting room.

I appeal to individuals and scientific societies that have decided to boycott Soviethosted scientific interchanges as a protest that they reconsider their decision. Boycotts do little to embarrass or punish the Soviet government for its repressive and reprehensible policies towards dissident scientists (writers, intellectuals, etc.); attendance at these scientific interchanges as representatives of free world countries may do much to assure the Russian scientific/ academic community of our awareness of their plight, and of our deep concern and sympathy for them. It lets them know of our resolve not to cut them off from new information from the outside world, but to share with them our scientific findings, our ideas, our literature, which they, like us, should not be denied. They are obviously not optimistic that things will change in the near future. Let us at least continue to help them endure what they must so that they can continue with their careers, with their scientific research which they love as much as we do. LEE FRANK

#### Not cricket either

SIR — Certainly the City of New York's Yankees deserve numerous boos and catcalls for their performance in the World Series. Just as certainly, your publication deserves similar treatment for printing a column ("Shame on New York", Nature 5 November, p.2) demonstrating both little understanding of the subject and a shameful neglect of facts evident to all but the most illiterate American youth.

You state "Part of the reason why the Yankees lost is that they were not as skilled at catching and throwing the ball as were the Dodgers", a glaring misstatement in light of the Dodgers' second baseman's infamous accumulation of six World Series records for "errors committed" (literally: failure to catch and throw the ball). In addition, claiming that there was "little to choose between the batting performance of the two teams" ignores the dismal failure of one of the Yankees' most depended-upon batters (Dave Winfield, playing under a multi-million dollar contract) to connect for more than one hit in twenty-two at bats during the series.

Concerns for propriety and my own temperament forbid me to further chronicle and refute the errors contained within the column. Allow me to end my tirade by pointing out your insensitivity in measuring the speed of a baseball in units of ''metres per second'' thereby violating the worshipful reputation of baseball as ''a game of inches''.

## NEWS AND VIEWS

# Consider the incompleteness of the geological record

from Tjeerd H. van Andel

For more than a century geologists have felt comfortable with the notion that geological processes, although very slow, are also steady and so capable of moulding the Earth given enough time. The steady drip hollows the stone. The idea of steadiness came, at least in part, in reaction to the catastrophist view of the early 19th century which saw the history of the Earth as punctuated by brief but violent upheavals separated by long times of unchanging tranquillity. The slowness was suggested by the difficulty of observing many geological processes at work, and was enhanced by the growing awareness of the great length of time that was available. The rise of a continent may not be visible in a lifetime, nor the removal of a mountain by erosion, but the 4.5 billion years of Earth history provide enough time for all recorded events.

In recent years we have learned that many, perhaps most, geological processes are more rapid than once believed. The Atlantic Ocean widens at a rate of 20 km per million years, the rise of sea level at the end of the last Glacial locally pushed the coast inwards at a rate of 3 km per century. Every year the Mississippi delta adds 50m of land to the state of Louisiana and, if left undisturbed, the equatorial ocean would fill with sediment in a few hundred million years. If these rates are typical, do we need all of the available time to account for the events recorded by the rocks?

The answer is clearly negative. Studies of modern depositional environments taught us the rates of deposition typical for each. We may apply these rates to the deposits left behind by their equivalents of the past if we make allowance for such matters as compaction due to overburden and time. For years I have been intrigued by the result of such estimates. In Wyoming, a sequence of early Cretaceous sandstones and shales closely resembles the coastal sediments of the present Gulf of Mexico. Applying the appropriate rates of deposition we find that a mere 100,000 years would suffice to produce the entire sequence. Yet the stratigraphical interval occupied by the deposits is quite firmly known to encompass about 6 million years. We may repeat the experiment elsewhere; invariably we find that the rock record

requires only a small fraction, usually 1 to 10 per cent, of the available time, even if we take account of all possible breaks in the sequence. Evidently deposition, unlike work in Murphy's law, does not expand to fill the time available. This might in principle be expected but the universality and especially the magnitude of the shortfall are startling.

This fascinating observation has attracted the interest of a few geologists but only in passing. Recently, however, it has inspired Peter M. Saddler to examine the issue in depth (Journal of Geology 89; 569, 1981). If it is indeed true that ancient sediments represent less time than available, the accumulation rate obtained by dividing the thickness of a deposit by the length of the interval it occupies ought to be smaller than the deposition rate measured directly in the equivalent modern environment. This, indeed, turns out to be the case and the fractions of time not represented by deposits are very large. Even more interesting, the massive amount of data put together by Saddler shows that accumulation rates (thickness/available time) are inversely proportional to the length of the interval over which they are estimated. This inverse relationship holds true for all kinds of environments, even though the precise form varies.

Because one can resolve very short intervals only in young deposits while very long ones carry us far into the past, one might surmise that what we are observing is a progressive increase in the rate of deposition towards the present. This assumption, unattractive for several good geological reasons as well, is incorrect because the inverse correlation exists between the accumulation rate (or the thickness of the preserved sediment) and the duration of the observed interval, but not its age. Thus it appears that indeed the geological record is exceedingly incomplete, and that the incompleteness is greater the shorter the time span at which we look.

Tjeerd H. van Andel is professor of oceanography in the Geology and Geophysics Departments at Stanford University, California.

It does not startle us that the geological record is damaged by gaps; we have known that for a long time. Nor is it surprising that the amount of time represented by breaks is significant. Some time ago, before the deep-sea drilling programme of the Glomar Challenger, it was widely believed that the sediment record in the deep ocean should be very complete because the environment is quiet and is the ultimate resting place of all debris. This turned out to be far from true. In the South Atlantic. for example, barely half of the history of the last 125 Myr is recorded in sediment. It is no better in other oceans and surely worse for shallow marine and continental environments. Even so, the level of incompleteness with which we are concerned in this paper is far in excess of what has been observed or might reasonably be anticipated.

If erosion and other ravages of time are the cause of the missing record, one should expect the incompleteness to increase with age. This, however, is not the case and the explanation cannot be so simple. Saddler's voluminous data show that shortfalls do not only occur on all time scales but that they are a function of the time scale. Taking a hypothetical fluviatile sequence 500 m thick and spanning 7.5 Myr, he shows that a reasonable annual deposition rate, in the flood plain of a permanent river for example, will produce this thickness in 5,000 years. The observed sequence would thus be 0.075 per cent complete. If, on the other hand, we use a deposition rate on an hourly scale, a flash flood perhaps, the section's completeness would be 1 in 10 million.

The consequences of the inferred severe incompleteness of the geological record and its relation to time scale deserve our most serious attention because they affect the history of the Earth in many ways. Consider, for instance, the desire to locate the real boundary between two stratigraphical rock units. The likelihood that such a boundary will have been preserved is much greater for units of long duration than for brief ones: our chance of finding the boundary between two strata of 5 Myr duration in an interval of 25 Myr is much greater than that of locating the contact between two beds each spanning 1

Myr. Conversely, if we believe that we have located the deposits associated with a brief event, an asteroid impact perhaps, in several stratigraphical sections, we ought to consider the extremely low probability that any event on a decadal time scale would be preserved at all, even once.

Many of the gaps in the record can be clearly seen, especially those on longer time scales, but the conclusion is inescapable that most breaks must go unnoticed. The geological record appears to consist of brief periods of activity separated by long times during which nothing happens or, alternatively, long times during which brief events leave minimal imprints which are removed by the next ephemeral event. However, even if only the occasional major event leaves a record substantial enough to be preserved, one would still like to think that the intervening times of erosion and non-deposition might leave some trace, a subtle alteration of the surface, a bit of soil formation, some burrowing. There is plenty of evidence that such effects exist and can be observed, yet most gaps must remain unmarked. I was much influenced early in my career by the recognition that two thin coal seams in Venezuela, separated by a foot of grey clay and deposited in a coastal swamp, were respectively of Lower Palaeocene and Upper Eocene age. The outcrops were excellent but even the closest inspection failed to turn up the precise position of that 15 Myr gap.

The geological record may thus be a record of rare events separated on any time scale by numerous and long gaps. Apart from the problems this presents in stratigraphy, there is no more cause for disquiet in this concept than there is in the atom model, also an object of little substance and much space. If the history of the Earth is mainly shaped by rare but major events, we need not greatly regret our inability to track the trivial day to day happenings. Intuitively, the notion seems plausible: nature all around us seems to change mostly by leaps. If at first sight such a record of history appears uncomfortably limited, like one of only battles and kings, two centuries of study have shown that it makes sense even in this abbreviated form.

There are, however, also disturbing aspects beyond the need of a vastly increased care in stratigraphy and chronology. Among the many ideas fermenting today in the study of evolution there is one, frequently heard, that ascribes the major evolutionary steps to a jump advance, a concentration of major change in a very brief interval of time. There seems to be no good reason why such pulses of evolutionary change should coincide with the major rare events that built the sedimentary sequence in which the record of evolution is contained. Thus, the new 'catastrophist' view of the sedimentary record implies that key elements of the evolutionary record may be forever out of

# A potpourri of plucked patches

by Henry A. Lester

HAMILL, Marty, Neher, Sakmann and Sigworth<sup>1</sup> and Horn and Patlak<sup>2</sup> recently described new techniques for improved recording from single ion channels in biological membranes. They also showed how to excise the membrane patch under study, so that the experimenter can manipulate the solution bathing either the cytoplasmic or the external face. These methods, described in a *News and Views* article by McBurney<sup>3</sup>, are leading to an explosion of new knowledge. The pace can be gauged by this review of six months' progress.

Studies on acetylcholine receptor channels have led the way. Two papers in this issue of Nature reveal that channel behaviour is more complicated than the former view of a simple transition to a unique open state with a smooth, featureless ion flux. First, Hamill and Sakmann (see p.462) shows that rat myotube channels have two open states that differ by several fold in their conductance. Channels open to the 'main' state, then hop (with a low probability) to the less conductive 'substate'. From the substate they can either close or return to the main level, with roughly equal probabilities. In addition to this wrinkle in the description of the open channels' conductance, the improved temporal resolution of the gigaseal technique has enabled studies on the fine structure of the gating events. The opening and closing transitions themselves require no more than 10µs so that complete events lasting just  $50-70 \mu s$  can be resolved. Colquhoun and Sakmann (see p.464) now report that the open state is indeed interrupted by events of this brevity when the agonist is suberyldicholine in frog muscle. On the average, a single open 'burst' is interrupted 3.1 times by gaps whose lifetimes are exponentially distributed with a mean of 150  $\mu$ s. The investigators consider the possibility that these Nachschläge represent the longsought transitions between the bi-liganded open and bi-liganded shut states. An additional, more subtle form of 'openchannel noise' can be observed in the patch-clamp records of other investigators. Such fluctuations probably do not arise at the single-ion level, but may be explained by motions of the amino acid side chains that presumably line the channel. If so, patch-clamp recordings provide an elegantly simple way to obtain information on the molecular dynamics of proteins.

The glutamate receptor channel of locust muscle weighs in with a hefty conductance of 125-150 pS. Recent patch-clamp investigations have sought to understand the basis for the sigmoid dose-response curve. With an elegant multibarrel internal

Henry A. Lester is in the Division of Biology at the California Institute of Technology.

perfusion system for the patch electrode, Cull-Candy et al.<sup>4</sup> found that the channel opening rate increases with the square of the glutamate concentration, suggesting that two glutamate molecules are required to open a single channel. Gration et al.<sup>5</sup> found that the mean channel duration also increases with [glutamate] as though all sites must be vacated to allow channel closing. It is not clear whether these two factors are compatible with each other; it is perhaps relevant that Gration et al. observed non-random features in the gating kinetics, suggesting as yet unexplained transitions in agonist affinity.

Electrically excitable Na+ channels are rather more difficult to study carefully because the open conductance is only 6-18 pS; depending on the conditions. Nonetheless it seems clear from the available recordings that the open Na+ channel does not flicker<sup>6,7</sup>. Horne et al. 7 compared the closing of channels which had opened either early or late during a depolarizing clamp pulse and obtained evidence for the view that activation and inactivation are independent processes, as in the original Hodgkin-Huxley formulation. However, macroscopic voltage-clamp experiments have for some time pointed to discrepancies between observed kinetic behaviour and that predicted by the Hodgkin-Huxley equations; and patch-clamp investigations now confirm that the open state lasts longer than would be predicted if the channel could be closed with equal probability by transitions in any of three putative subunits. Apparently the closing rate is limited by the last transition preceding the open state in the activation pathway, a conclusion that is particularly clear when the inactivation pathway has been removed by exposure to N-bromoacetamide8.

In almost every type of cell that has been patch-clamped, the investigators were startled by enormous signals that took the oscilloscope trace off screen. Upon further investigation these signals were recognized as Ca2+-activated K+ channels (chromaffin cells9, myotubes10, autonomic ganglia11, Helix neurones19 human erythrocytes<sup>12</sup>). These channels have conductances of 100-200 pS and show very interesting flicker and open channel noise. The opening rate increases with both [Ca2+] and depolarization, with an absolute requirement for Ca2+, as though the membrane potential is influencing the effective affinity constant for Ca<sup>2+</sup>. It would be most interesting to know (a) the Hill coefficient for the doseresponse curve and (b) whether the channel still functions after procedures that remove calmodulin from the membrane.

Other potassium channels have been observed with the patch clamp. Ohmori et

al. 13 recorded inward ('anomalous') rectifier channels on myotubes as they flickered due to the binding and dissociation of Ba2+ ions. conductance (10pS), kinetics and voltage sensitivities agree well with results from noise and voltage-jump relaxations. However, at the recent Neuroscience meetings H.C. Hartell reported that muscarinic agonists induce surprisingly brief K + channels in cultured heart muscle. The average duration is 37ms or about a tenth as long as the time constant derived from fluctuations14, voltage-jump relaxations<sup>15</sup>, or concentration-jump relaxations<sup>16</sup>. The channel conductance is 8pS. Hartzell speculates that the slow macroscopic relaxations derive from repeated binding of agonist to receptors, leading to multiple channel activations.

There's more. Bormann et al. 17 recorded

single GABA-sensitive channels in excised membrane patches from cultured spinal cord neurones. The channels are selective for chloride and have a conductance of 23pS. And Lux and Nagy<sup>18</sup> observed single Ca2+ channels in Helix neurones. The opening rate increases with depolarization; the channel duration (about 25ms), on the other hand, shows no voltage dependence. The conductance of 5-15 pS is much larger than expected from noise measurements but exact comparisons could be misleading because the Ca2+ channel is not ohmic.

Patch-clamp recording are so easy (compared with conventional voltage clamp experiments), and so immediately gratifying, that we are incorporating them into an undergraduate laboratory course at Caltech. The only specialized instruments required are a high-quality microforge and a carefully engineered headstage (now

available from several manufactures). Data analysis is tedious and time-consuming, but this will undoubtedly not prevent a host of interesting and important investigations with the new techniques.

# T lymphocytes: repertoire and recognition

Any discussion of T cell immunology sooner or later leads to controversy. Although T cells, like B cells, are capable of recognizing foreign antigens with exquisite specificity, the nature of their activation is far less well understood. First, they are a heterogeneous population pursuing both effector and regulatory functions, recognizing mainly membrane-bound antigens, and second, they are restricted to seeing antigens in the context of molecules of the major histocompatability complex (MHC). This has been one of the most exciting findings in immunology in recent years and raises questions of how both a foreign antigen and a MHC molecule in the same membrane can be recognized by a single T cell and why activation results only when both are present. Whether one or two receptors are required for the recognition step is hotly debated and the mechanism by which such a sophisticated repertoire develops within each individual is also in dispute. It was with these two major questions in mind that many workers in the field were recently invited to a workshop in Rüdesheim in Germany\*.

#### Ontogeny of the T cell repertoire

The T cell repertoire is constrained both by the requirement of MHC restriction and by the need to remove or inactivate, early in development, T cells capable of responding to normal antigens found on the cells of the individual. This 'learning' process has been believed to occur in the thymus but recent studies of the congenitally athymic nude mouse are raising some questions. Nude mice have T precursor cells but the development of the repertoire is deficient. H. Wagner (Johannes-Gütenberg University, Mainz) and T. Hünig

(University Würtzburg) reported the generation in vitro of cytotoxic T cells from precursors found in both normal and nude mice, but the nude mouse was deficient in precursors against certain antigens. J.C. Cerottini (Luding Institute), using similar techniques, found only quantitative differences between the two animals although nobody has yet been able conclusively to demonstrate functional helper T cells in the nude mouse. The precise immunological status of the nude mouse is therefore still not clear but the existence of at least some precursor T cells which can be stimulated in vitro suggests that some pre-thymic development of the repertoire may occur. A. Singer (NIH) described experiments specifically designed to test this hypothesis. He constructed chimaeras using an  $(A \times B)$  F. host, thymectomized, lethally irradiated and grafted with an A thymus and A bone marrow, whose recovered thymocytes were shown to be tolerant to B MHC determinants. This suggested that tolerance had been induced prethymically and some pre-T cells at least must already have learned self MHC. Support for extrathymic development of some precursor T cells also came from experiments reported by R. Miller (Ontario Cancer Institute, Toronto) who described a novel culture system for generating T cell colonies from single immature precursor T cells which were MHC restricted but surprisingly developed several antigen specifities.

On the other hand, transplantation experiments have shown that the thymus does exert a significant but as yet unclear effect on the generation of the T cell repertoire. It is thought that the thymic epithelium may act by presenting antigens and self-MHC molecules to T precursor cells after which selected clones are stimulated to develop to maturity. I. Weissman

University) presented provocative data on the discrete distribution of different classes of MHC molecules in different regions of the thymus, but there is as yet no firm evidence of a common pathway by which T cells pass through the thymus and undergo step by step acquisition of the repertoire in the normal animal. Clearly new approaches are required and R. Jordan (Newcastle University) presented interesting preliminary experiments using cold treatment of thymuses in vitro to obtain pure thymic epithelium which may be useful in understanding its role in antigen presentation.

The picture emerging seems to be that the thymus acts on T cells to select precursors which are restricted to recognizing antigen in conjunction with self-MHC molecules and to expand this population, possibly by an interleukin-2 signal. Some clones, however, may develop outside the thymus without having been selected to see antigen only in conjunction with self-MHC molecules. It may be that this population does not receive an inductive signal and so remains in low numbers in the normal animal, overshadowed by the thymic-processed, self MHC-restricted population.

The experiments described by Z. Nagy (Max-Planck-Institut, Tubingen) were very interesting in this respect. He has been looking at the phenomenon of low responsiveness which is found in specific mouse strains against certain antigens. In an in vitro system he has shown that T cells from a low responder strain can respond to the antigen if it is presented by (non-self) antigen-presenting cells. This suggests that there are two compartments in the T cell repertoire, one that recognizes foreign

Nigel Williams is a member of the editorial staff of Nature.

<sup>\*</sup>A workshop on 'The role of the thymus in the T cell repertoire' was held in Ruderheim on 16-19 September 1981 organised by the Johannes-Gutenberg-Universitat, Mainz and sponsored by the Deutsche Forschungsgemeinschaft.

antigens in the context of self-MHC molecules and another that can use allogeneic MHC molecules of the species for the context of antigen recognition. However, it seems that in the mice of the low responder strain, clones capable of responding to the antigen in the context of self MHC are absent. Such experiments emphasize the importance of MHC molecules in the generation of the repertoire and raise difficult questions about the nature of antigen recognition by T cells.

#### T cell-antigen interaction

There are two opposing theories of how individual T cells recognize both MHC molecules and a foreign antigen (X) — one model requires two separate receptors and the other, the interaction antigen model, has recently been argued by Matzinger (Nature 292; 497, 1981). This model proposes that MHC molecules interact with antigen X and are presented as a single entity to a single T cell receptor. In its most provocative form it proposes that the interaction of specific self-MHC molecules with a particular antigen X will give rise to a new antigenic determinant expressed only by the interacting complex. A prediction of the interaction antigen model is that crossreactivity with allogeneic MHC + antigen Y could occur, for example if the allogeneic MHC + antigen Y interaction produced an antigenic determinant cross-reactive with those of a self MHC + antigen X interaction. Since the cross-reactive determinants are absent from the individual non-interacting components, then if the T cell recognizes both entities via separate receptors cross-reactivity would not be expected. T. Hünig (see this week's Nature, p.460) presented experiments showing that indeed a small proportion of clones of T cells specific for self MHC + X showed reactivity against allogeneic MHC + Y under some conditions. R. Schwartz (NIH) and C. Janeway (Yale University) also reported the generation of self MHCrestricted clones specific for antigen X which showed a degree of cross-reactivity with allogeneic MHC molecules.

Another prediction of the interaction antigen model is that T cells will have no particular specificity for self-MHC molecules or antigen X alone, being specific only for a combination of the two components, whereas with the two receptor model T cells should bear separate receptors for antigen X and for MHC molecules. H. Cantor (Harvard University) presented data from a T cell clone specific for self MHC + X (in this case, cow insulin) which secreted a 68K molecule into the supernatant. The molecule bound to other related insulins with a lower but particular affinity — when passed through columns each containing a different insulin, it was recovered in the same proportion as predicted by its binding affinities. A column containing the specific restricting MHC molecules failed to bind the molecule. If this molecule is part of the

T cell receptor (which is uncertain at this stage), then a degree of independence of the antigen-binding component and the component specific for the restricting MHC molecules is suggested. If the two components are indeed presented as an interaction antigen it must be of the very loosest kind. R. Schwartz interpreted these data in terms of a single receptor which has two separate binding sites with different specificities. This could possibly explain how a receptor specific for self MHC + X could recognize allogeneic MHC molecules if these were sufficiently structurally different to make contact with both binding sites sufficient to activate the cell.

Clearly we need to know a great deal more about the precise role of MHC molecules in T cell responsiveness. To this end G. Hämmerling (Cancer Research Center, Heidelberg) showed that different T killer cell clones restricted to the same MHC molecule could be blocked from responding by monoclonal antibodies to different determinants on the MHC molecule. Until we know more precisely the function of MHC molecules, the manner in which a single T cell sees both MHC molecules and a foreign antigen is likely to remain controversial and immunologists will still not know if 1 + 1 = 1 or 2.

# Receptors, channels and whole-body NMR in Mexico

from M.J. Geisow and J. Mas-Oliva

THE 7th International Biophysics Congress and 3rd Pan-American Biochemistry Congress was held in Mexico City recently. Despite the title, no dichotomy was obvious — it is now impossible to distinguish biophysicists from biochemists on the basis of project or hardware. Many topics were covered, but a dominant theme was the measurement, biochemical analysis and functional implications of ionic gradients across cell membranes.

An understanding of transduction or ion transport through biomembranes can only come through knowledge of the structure of intrinsic membrane proteins. As yet, no example exists, whether receptor, channel or carrier, where structural determination is sufficiently advanced to allow firm conclusions about mechanism. This situation was not changed in Mexico, although bacteriorhodopsin is clearly a front runner with a tentative assignment of amino acids to the 3Å analysis and extensive work on reconstituted rhodopsin systems.

Also promising is the F<sub>1</sub> structure of proton-translocating ATPase (F<sub>1</sub>.F<sub>o</sub>) reported by Amzel et al. (Johns Hopkins University) at 9Å resolution. Three large domains, related to a similar triplet by local symmetry, seem likely to reveal the location of the five types of polypeptide as well as the ligand and effector sites. The protonophoric (F<sub>0</sub>) membrane-embedded chains may consist of a hairpin arrangement of twin helices (Sebald and Hoppe, Technical University of Braunschweig). They bear a buried, invariant acidic amino acid the loss of which, by modification or mutation, halts proton translocation.

M.J. Geisow is in the Biophysics Department, National Institute for Medical Research. J. Mas-Oliva is in the Biochemistry Department, National Institute of Cardiology, Mexico City. Another close contender is the acetylcholine (ACh) receptor, reviewed by J.P. Changeux (Pasteur Institute, Paris). The minimum functional aggregate (in reconstitution experiments) consists of four glycosylated peptides:  $\alpha(40K)$ ,  $\beta(50K)$ ,  $\gamma(60K)$  and  $\delta$  (65K) in 2:1:1:1 stoichiometry and having NH<sub>2</sub>-terminal sequence homology.  $\alpha$  is labelled by AChreactive analogues,  $\beta$  by channel blockers (such as histrionicotoxin). Three molecular transitions of the complex, revealed by bound fluorescent agonists, may be associated with a minimum of three pharmacological 'states' of the receptor.

The sodium channel of neuronal plasma membranes is more elusive. Miller and Agnew (University of Colorado) have studied a  $260,000-M_{\tau}$  tetrodotoxin-binding component of the channel complex. The binding properties of this highly charged glycoprotein are particularly sensitive to the lipid microenvironment.

Working with sarcolemma, Almers et al. (University of Washington) established that sodium channels are relatively immobile in the bilayer. Their local destruction in a clamped patch of membrane by UV photobleaching leads to loss of sodium conductance for one hour. Channels are refractory to laterally applied electric fields and are considered to be 3 orders of magnitude less mobile than rhodopsin.

The strong probability that other channels and receptors are anchored to the cytoskeleton also emerged. The ACh receptor seems to be fixed so firmly in the membrane by an alkali-extractable 43,000-M<sub>r</sub> component (not actin) that the addition of exogenous lipid leads to rafts of receptor aggregates, rather than randomly dispersed molecules. Cherksey and Zadunaisky (State University of New York) used the fluorescence of propanalol

as a probe for the mobility of the  $\beta$ -adrenergic receptor in the presence and absence of microfilament-disrupting drugs and conclude that the receptor is anchored to the cytoskeleton.

A steady improvement in the quality of 'model' membranes is taking place at the same time as the successful extraction and characterization of intrinsic membrane proteins. M. Montal (University of California) has developed a technique of spreading two monolayers of protein and lipid and apposing them across an aperture to form a planar bilayer. H. Schindler (University of Basel) employs the same technology, but has discovered that natural membrane or lipid vesicles, added to the aqueous compartments, are in equilibrium with and contribute representative lipids and proteins to the surface monolayers.

The functional reconstitution of membrane proteins will allow two persistant problems to be addressed. First, what, if any, is the influence of particular lipids on protein function? and second, what role is played by protein-protein interaction in the bilayer? P.F. Devaux (Pasteur Institute, Paris) has devised spinlabelled lipid probes which covalently attach via their head groups to reconstituted membrane proteins. This achieves a significant increase in occupancy by probe of the protein-lipid boundary. Rotational correlation times of the proteins obtained in this way indicate strong lateral interactions (proteinprotein) for ACh receptor and Ca2+-ATPase and very weak ones for rhodopsin. Spin exchange between boundary probe and lipids spin-labelled with a different nitrogen isotope show that migration of lipids into the lipid boundary of rhodopsin is independent of the head group.

Lateral interactions between the intrinsic membrane proteins of the inner mitochondrial membrane were explored by C.R. Hackenbrock (University of North Carolina). Electron transfer between the various oxidation-reduction complexes and carriers appears to be facilitated by the gregarious nature of the proteins. However, although electron transfer decreases monotonically with the addition, by fusion, of exogenous lipid, it does not cease. Freeze-fracture of vesicles reveals uniform dispersion of all particles (proteins) in lipid-enriched membrane vesicles. Antibody marker techniques demonstrate that cytochromes oxidase, b and c do not migrate as complexes. In fact, sufficient diffusional motion (measured by freeze-fracture of vesicles after relaxation of an electric field) of the intrinsic proteins can occur within one turnover of reducing equivalents to render stable proteinprotein interactions unnecessary.

Another role hypothetically associated with lateral interactions of intrinsic membrane proteins is the formation of an ion pore/channel in response to an associating stimulus. Montal and Borochov-Neori (University of California)

examined whether vertebrate rhodopsin mediates changes in membrane ion permeability by aggregation following the light-dependent conformational change of the molecule. Conductance characteristics of planar bilayers containing rhodopsin support this view of channel formation. However, the alteration in aggregation state after bleaching (determined by fluorescence-energy transfer between rhodopsin monomers) is more subtle than expected.

Cast in the role of principal information carrier associated with the operation of membrane channels, ionic calcium continues to attract much attention. The eager studies of the action of intracellular calcium have often overshadowed the more sober, but hardly less important, investigation of its intracellular regulation. Although there is still confusion and controversy about how calcium enters the cytoplasm, steady progress has taken place in measuring it when it is there and on how it is removed to return the cell to a resting state. For example, using permeant fluorescent calcium indicators synthesized by R.Y. Tsien (University of Cambridge), resting lymphocyte calcium ion was measured at 0.12 µM.

For the extrusion of calcium ions, two plasma-membrane processes are available: a Na<sup>+</sup>/Ca<sup>2+</sup> exchange protein and a

calcium-stimulated ATPase. Blaustein and Nelson (University of Maryland), DiPoldo and Beauge (Caracas and Cordoba, Argentina) and Caroni and Carafoli (University of Zurich) all described a calcium removal process operating at very low levels of Ca<sup>2+</sup> (down to 0.1μM), fueled by ATP. However at high Ca<sup>2+</sup> (up to 10 μM), Na<sup>+</sup>/Ca<sup>2+</sup> exchange was dominant. The latter authors reported that the cardiac muscle sarcolemma Na<sup>+</sup>/Ca<sup>2+</sup> exchanger swops 3Na<sup>+</sup> for 1 Ca<sup>2+</sup> (requiring a counterion) and is insensitive to calmodulin, unlike the Ca<sup>2+</sup>-ATPase.

High intracellular Ca2+ was formerly thought to regulate the permeability of the intercellular gap junction. As related by M.V.L. Bennett (State University of New York), the association constant for this process is unphysiologically high (K =0.4mM Ca2+). In single pairs of embryo blastomeres connected by gap junctions, conductance is regulated by a process with a  $pK_a$  of 7.3 (the channels are closed when the cytoplasm is slightly acidic). Voltage clamping the cells at different levels, thus forcing a transjunctional potential, also closes the channels. These two control processes are not the same, since aldehydes selectively block the pH dependence.

Work on the mammalian liver cell gap junction has also progressed well; a hexameric array of protein units spans the

#### POPULAR NATURAL HISTORY

We give, through the courtesy of the publishers, another illustration taken from the chapter on Weevils. It is of a weevil known as Rhyncophorus palmarum. Its fat grubs live on the stems of palmtrees, and are often very destructive. Several of the species are very injurious to the sugar-cane. One found in sugar-plantations in Guiana contain in their intestines lumps of a sweet waxy substance - the altered saccharine food on which they live - and for this they are boiled and eaten by the native. The fine fat larva and the pupal condition, as well as the full-grown weevil, are to be seen in the engraving.

From *Nature* **25**, 109, December 1, 1881.

membranes of the communicating cells. B. Zampighi (UCLA) described a new iunction for eye lens fibre membranes. At low resolution, the protein subunits are tetramerically arranged, unlike the conventional gap junction.

Many functions of intrinsic membrane proteins depend on ATP, and in the last

session delegates were rewarded with the sight of NMR spectrometers built to measure ATP in most parts of Britton Chance's anatomy. The impact of this lecture was certainly magnetic and the closing slides of the ultimate biophysical conjunction, man and machine, were a fitting way to end the Congress.

# Control of a mixed tRNAprotein operon

from Andrew Travers

DURING exponential growth the bacterium Escherichia coli balances the production of ribosomes and other necessary components of the translation machinery of the cell so that no more ribosomes are produced than are required for the maintenance of growth. To achieve this balancing act the synthesis of the stable RNA species, rRNA and tRNA, must be accurately coordinated with the synthesis of both ribosomal proteins and the cycling translation factors. One such protein is the elongation factor Tu (EF-Tu) whose function is to bind charged tRNA and facilitate its engagement in the acceptor site on the ribosome as a prelude to peptide bond formation. Accordingly, the amount of EF-Tu in the cell parallels that of tRNA. The protein is one of the most abundant in E. coli comprising up to five per cent of the total cellular protein and is encoded by two distinct genes, tufA and tufB, whose products differ by only a single amino acid1,2.

The major gene for EF-Tu, tufA, is expressed at  $\sim 2.5$  times the rate of tufB, and is located in the centre of a cluster of r-protein genes with which it is cotranscribed. This arrangement is typical of r-protein genes in general. By contrast, recent work by three groups3-5 has demonstrated that tufB is not associated with other r-protein genes but instead is cotranscribed with a neighbouring group of four tRNA genes, thrU, tyrU, glyT and thrT. This transcription is directed by a promoter lying upstream of the tRNA genes and is terminated immediately distal to the tufB gene. Although cotranscription of tRNA and protein genes has previously been observed in mitochondria this is the first report of this type of gene organisation on the bacterial chromosome. Moreover Hudson et al. (see this issue of Nature p.422) suggest that this example is not unique and that the tyrT transcript may encode both two tRNA<sub>1</sub>Tyr sequences and a small arginine rich protein. In this case, however, the evidence for the production of such a protein in vitro remains to be established.

What is the functional significance of the

Andrew Travers is a staff scientist at the MRC Laboratory for Molecular Biology, Cambridge.

co-transcription of stable RNA and r-protein genes? Hudson et al. advance two possibilities. The presence of a tRNA structure immediately preceding the tufB coding sequence could enhance the stability of the tufB mRNA. For this hypothesis the in vivo evidence offers as yet little support. Alternatively, the cotranscription of tRNA and mRNA would result in a measure of coordinate regulation. The transcription of both stable RNA and r-protein mRNA species is regulated both by the availability of amino acids and by variation in growth rate. In vivo, sudden amino acid depletion results in a drastic curtailment of the production of all major components of the translation machinery. This stringent control is mediated largely at the level of RNA chain initiation and is associated with the presence of a G+Crich discriminator sequence located close to the start point of transcription.

In addition, promoters regulated in this mode often, but not invariably, contain extensive regions of dyad symmetry. The promoter for the tRNA - tufB transscription unit contains both these features and is indeed controlled stringently both in vivo6 and in vitro4.

For control by amino acid availability, the co-transcription of stable RNA and an r-protein mRNA is logical. However, a paradox is apparent when the linkage of transcript production to growth rate is considered. As the growth rate of a bacterial culture increases there is a proportionate increase in the number of ribosomes per unit amount of total cellular protein. Since the ratio of production of total protein increases in direct proportion to the growth rate (µ) the synthesis rate of both stable RNA and r-protein must increase approximately in proportion to  $\mu^2$  to yield a preferential enrichment of ribosomes. However, whereas the transcription of both rRNA and the most abundant tRNA species follows this latter pattern that of r-protein mRNA does not, increasing only in direct proportion to  $\mu$  (ref.7). Thus the growth rate dependent regulation of r-protein synthesis is probably mediated by post-transcriptional controls, including the feedback inhibition of r-protein mRNA translation by free r-proteins. By fusing

rRNA and r-protein promoters to the coding sequence for galactokinase or B-galactosidase Miura et al. 8 have recently demonstrated that the growth rate dependent regulation of transcription is programmed by the promoter region and thus probably reflects variation in rate of RNA chain initiation.

This pattern of differential initiation at stable RNA and r-protein promoters raises the question of whether the growth rate regulation of transcription of the mixed tRNA-tufB operon resembles that of r-protein mRNA or of stable RNA. Whatever the answer it is apparent that regulation of at least one portion of the operon would be anomalous.

No direct evidence bears on the question nor does the tufB promoter sequence offer any obvious clues. However, the function of the tRNA products of the operons favours the possibility that the whole operon is regulated in the r-protein mode. At high growth rates the r-proteins comprise the major class of proteins synthesised in the bacterial cell. Their translation, as well as that of EF-Tu itself, 1.2 preferentially utilises a limited subset of possible codons. Thus those tRNA species which recognise the codons included in this subset will be required in high amounts at high growth rates. Of the tRNA species contained within the hybrid operon two, the products of thrU and glyT. do not utilize the preferred codons. A third, the product of thrT, does recognise codons in this class but is the minor species of the two tRNAThr isoacceptors which do so. Thus there is no obvious requirement for the products of these three tRNA genes to be preferentially synthesised at high growth rates. However, the product of the fourth tRNA gene, tyrU also utilizes a preferred codon and is 1.5 times as abundant as the product of the second tRNATyr gene, tyrT. Nevertheless, the tyrT gene contains two copies of the tRNA sequence in a single transcription unit, an arrangement similar to that for the major tRNAGly, a tRNA utilized preferentially at high growth rates. Thus with the possible exception of the tyrU product all the products of the mixed operon, both tRNA and protein are minor components of mixtures of molecules of similar function. Such a situation would be more compatible with the pattern of r-protein regulation than with that of stable RNA regulation. In accord with this possibility the production of the tufB is less sensitive to amino acid depletion than is the tufA product6 and so would be favoured under conditions of growth rate limitation imposed by lack of amino acids.

# The geological exploration of Tibet

from A.M.Celâl Sengör

Owing to its unique physiography, geographical location and culture, the Tibetan Plateau has long attracted international scientific interest. Tibet owes its uniqueness to its very high elevation (~ 5 km above sea level), its vast areal extent ( $\sim 2.5$  million km<sup>2</sup>) and its position in the rain shadow of the Himalayan Range (Fig.1). Tibet's elevation has been attributed to a double thickness (~ 70 km) of continental crust underlying it1, but the precise mechanism for the development of this thick crust and the elevated plateau has been hotly debated. The lack of data from Tibet has been the chief factor in allowing widely divergent opinions to be held on even the most critical scientific questions concerning it.

A number of European and Sino-European scientific expeditions penetrated Tibet during the last decade of the 19th and the first four decades of the 20th century and gathered a large amount of data, pertaining to various disciplines, before such expeditions became impossible owing to the political changes in the area. The great scientific value of Tibet is appreciated by the Peoples' Republic of China, as evidenced by the number of diverse Chinese expeditions devoted to the exploration of Tibet since 1951. From 25th May to 14 June 14th, 1980, Academia Sinica organized a multidisciplinary, international symposium, including a field excursion on the Tibetan Plateau, both to report the results of the three-decade-long Chinese studies to the international scientific forum and to exchange opinions with their foreign colleagues<sup>2,3</sup>. The symposium ended with mutual wishes for future scientific collaboration.

The three papers in this issue of *Nature* (see p.405–417) by a Franco-Chinese team report the preliminary results of a three-month field trip in Tibet in the summer of 1980 and represent the first fruits of the renewed cooperative efforts of Chinese and foreign scientists in Tibet. Because so few foreign scientists have been to Tibet, let alone worked in it, the Franco-Chinese cooperation and the publication of its initial results in a language easily accessible to foreigners is of great importance.

The problems that most students of Tibetan geology are currently trying to address can be divided into two major groups. (1) Although there is general agreement that the basement of the Tibetan

A.M. Celâl Sengör is in the Geology Department of the Technical University of Istanbul and would like to thank Esen Arpat for his help in the preparation of this account.

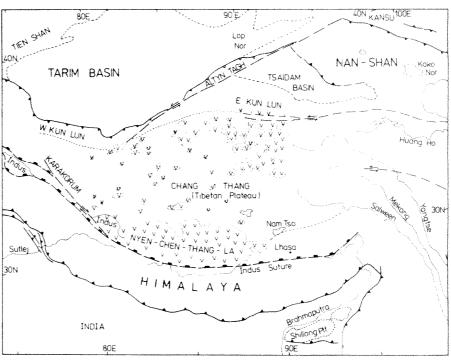

Fig. 1 Tectonic sketch map of the Tibetan Plateau and surrounding areas. Lines with black teeth are active thrusts around the plateau, lines with open teeth are inactive thrust boundary. v = Neogene and younger volcanic rocks (from ref. 11).

Plateau is composed of a small number (two?) of blocks that detached from the northern periphery of Gondwanaland and subsequently accreted to Asia, the exact history of these events is still a matter of conjecture. The elucidation of this history and the sequence of events that accompanied the India-Eurasia convergence, and their precise timing, constitute what I call the first-order palaeotectonic problems of Tibetan geology. (2) It is clear that the evolution of the present Tibetan high plateau is somehow related to India Eurasia collision during the early Tertiary1, but exactly how has been and still remains the question. This seems to be the first-order neotectonic problem of Tibetan geology. The three papers in this issue deal with both groups of problems in their study areas and also make some generalizations that pertain to the entire plateau.

Tapponnier et al. (p.405) review the background and general results of the cooperative field-work in southeastern Tibet. Their stratigraphical observations on the Lhasa Block are consistent with the earlier inference that this block, bounded in the north by the Tanggula suture of late Jurassic-early Cretaceous age and in the south by the Yarlung-Zangbo suture of early Tertiary age, was, until the Triassic, a part of Gondwanaland. The most

interesting novelties reported are those that pertain to the evolution of the Yarlung-Zangbo suture, the lineament that marks the line of apposition between the Indian sub-continent and Eurasia following the late Cretaceous-early Tertiary demise of Neo-Tethys. Tapponnier et al. argue that the structural evolution of the Yarlung-Zangbo suture involved four distinct episodes of deformation in the region they studied. Although the precise timing of these episodes and that of the emplacement of the Yarlung-Zangbo ophiolites remains controversial, the kinematic sequence they describe is a considerable advance. Their discovery of the apparent continuity between the epi-ophiolitic pelagic sediments and the unconformable clastic cover of the Gangdise granodiorites strongly supports the earlier interpretations of the Xigatse basin as a fore-arc basin<sup>2,4</sup> and indicates that it probably had an ophiolitic basement. They also underline the importance of the distinction between the Triassic passive continental rise approns2 (under the unfortunate designation "Triassic Flysch") and the Cretaceous wildflysch linked to orogenic deformation. Although there is sufficient evidence to the contrary, Tapponnier et al. reiterate the peculiar view that the Gangdise Andean-type arc might equally well have been an island arc!

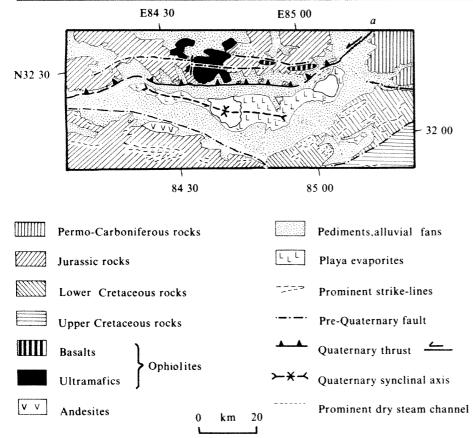

Fig. 2 1:1,000,000 geological map of the Zhaxi Co area drawn from Landsat image no. E-2664-04045-6 01 and sheet 6 of ref.15. White areas are present lakes. a is the strike-slip fault that seemingly connects with the Zhaxi Co thrust, the north-east continuation of which is particularly visible on Landsat image no. E-2663-03584-6 02.

The ophiolites of the suture zone themselves, as exemplified by the Xigatse ophiolite massifs, are interpreted to be unusual examples in the paper by Nicolas et al. (see p.414 of this issue). They note the greatly reduced thickness of the mafic part of the sequence, which is almost devoid of cumulate gabbros. The serpentinized ultramafic part is invaded by numerous diabase sills after the onset of serpentinization. Nicolas et al. prefer to interpret the Xigatse ophiolite as a possible product of a very slowly spreading ridge, although some of the reported peculiarities of this ophiolite complex, particularly the thin mafic section and the late intrusion of diabase into the ultramafic foundation invite suspicion in terms of a near-fracture zone ophiolite<sup>5,6</sup>.

Finally, both papers by Tapponnier et al. emphasize the east-west extensional nature of the Quaternary and also possibly late Tertiary deformation both in the region visited in particular and in Tibet in general, in full agreement with the long declared view of some of the French members of the team<sup>7,8</sup>. They note the decreasing intensity of north-south compressional deformation in southern Tibet since the late Cretaceous and underline the total absence of any Quaternary compressional features such as thrusts or folds in the areas studied. The significance of these preliminary observations increases by the fact that they seem to contradict the views of some Chinese9 and foreign10,11 workers who argue for the existence of Quaternary north-south shortening in Tibet. In fact the most recent geological map of Tibet12 shows a number of east-west striking faults cutting Quaternary deposits in southern Tibet and a few folded areas of Quaternary limnic and fluvial sediments. Figure 2 shows perhaps the most convincing case for Quaternary (active ?) thrusting in Tibet, in the area of Zhaxi Co. On sheet 6 of the 1:1,5 million geological map of Tibet<sup>12</sup>, Zhaxi Co is shown to have perched in a Quaternary syncline. On Landsat images the Zhaxi Co depression is seen to be overriden from the north along a northconcave thrust, which, towards the east, seems to connect with a very prominent east-north-east-striking, left-lateral strikeslip fault (a in Fig. 2) with several sag ponds, dry stream channels bent in an anticlockwise fashion and a very pronounced rift topography. All these structures are very young, if not active. The Zhaxi Co thrust may possibly continue westwards, in the direction of Gerze. Towards the east it is on strike with Siling Co, which is a Neogene (and younger?) ramp basin (Chen Zhi-ming, personal communication, 1980), and with the 1972. 7. 22. earthquake (epicentre 31.4 °N, 91.5 °E) which occurred on an east-west thrust13. All of these very young thrusts seem to be aligned along the trace of the Tanggula suture and

may represent its local, young reactivation. All such observations clearly indicate that the statement "in the Quaternary, deformation of Tibet was characterized by east-west extension" (Tapponnier et al. p.405) may not be descriptive of the entire picture and the comparison of Tibet with such dominantly extensional regions as the Basin and Range and the Aegean, both characterized by thinned crust, may not be exactly appropriate.

Tapponnier et al. also emphasize the "comparatively small amount of shortening and deformation of the surface sediments" north of the Yarlung-Zangbo suture. It would be of great interest to see the actual data and their quantitative results regarding local, observed values of stratal shortening. Because compressive deformation that results in buckle folding is often accompanied by about 10 per cent bulk shortening and thickening before folding occurs, such observations on folding alone always render a minimum value for shortening.

In conclusion, one cannot overemphasize the significance of the recent resumption of Chinese and foreign cooperation in the geological exploration of Tibet. As the papers in this issue and this commentary clearly show, Tibet has a multitude of unsolved yet critical geological problems, the better understanding of which would not only further our knowledge of the regional geology and evolution of this unique structure but would also contribute greatly to our understanding of such fundamental geological problems as continental collision, behaviour of the continental lithosphere, differentiation of the continental crust, and a host of other, smaller ones. No amount of experience and expertise could be too much to bear on such gigantic and diverse problems and if only on these grounds alone the work of the Franco-Chinese team is to be applauded. One hopes it will continue, and other similar efforts be made in the future, to illuminate both the palaeo-and neotectonic problems of Tibet.

Results are reported from the 1980 joint French-Chinese field expedition in Tibet. The area covered was from the High Himalaya in the south, to the region of Nagqu ~250 km north of Yangbajain. Ophiolites in the Zangbo valley represent remnants of the crust of an ocean basin which lay adjacent to the Gangdise granodiorite belt in the late Mesozoic. The ophiolites were thrust to the south onto the Cretaceous mélange and Triassic flysch but the age of this event is unclear. In the Tertiary, sediments of the Indian margin and the Xigaze basin were folded with steeply dipping cleavage, which indicates some north-south shortening of the crust. However, the Tertiary volcanic sequence on the Lhasa block and further north shows comparatively little folding and thrusting. In the Quaternary, deformation of Tibet was characterized by east-west extension.

TIBET has been much studied by geoscientists of the People's Republic of China, particularly in the past decade. Important results of these studies have been presented in two recent symposia. These results<sup>1-7</sup> and new maps at a scale of 1/1,500,000 (produced by the Ministry of Geology) provide a good geological data base for a country which is otherwise largely unknown in the west.

The French-Chinese joint study of the 'geological structure, formation and evolution of the Earth crust and upper mantle of the Himalayas' which began with three months of field work in the summer of 1980 provided the first opportunity for western scientists to work in Tibet since explorations at the beginning of this century<sup>8-12</sup>. Hence the results presented here are merely an extension of the Chinese work (see, for example, refs 13-15).

We summarize here preliminary field reports jointly prepared by French and Chinese geoscientists. More detailed accounts will be published elsewhere 16-20. The joint study was limited to a region north of the Himalayas between Zham and Lhozhag, and south-west of Nagqu (~250 km north of Yangbajain). [Note that geographical names are spelled according to the Ping Yin transcription on the most recent maps published in the People's Republic of China: Jiang means river in Chinese and Co, lake in Tibetan.] Some of us (P.T., F.P., X.X.C.) went close to the border with Qinghai, on a reconnaissance trip.

Several important questions about the evolution of Tibet remain essentially unanswered. For example, although there is little doubt that the geology of Tibet was shaped in the Mesozoic by successive collisions with Laurasia of different blocks previously detached from Gondwana<sup>13,21,22</sup>, it is not known precisely how and when the different basins of the Tethys opened and closed. Similarly, although the high and apparently recent elevation of the Tibetan plateau must be related to the collision and penetration of India into Asia<sup>23,24</sup>, detailed field studies of this large and harsh territory are inadequate for a choice to be made between two extreme models—that of Argand<sup>25</sup>, who postulated that Tibet is largely underthrust by the crust of northern India, and that of Dewey and Burke<sup>26</sup>, who suggested

that Tibet has shortened and thickened more homogeneously (like an accordion) during the late Tertiary.

Our main aim was to improve the understanding of the local geology by using new techniques and observations and to integrate our observations into the framework of plate tectonics.

#### Sedimentation changes on the Lhasa block

The stratigraphy of the Lhasa region <sup>1,2,7</sup> has been investigated in particular detail near Linzhu (Fig. 1). North and west of Linzhu, the probably Precambrian metamorphic basement (two mica gneisses north of Machu) is covered by Carboniferous tillites (pass north of Linzhu) with Gondwanian affinities. Shallow marine sedimentation dominates from the Permian to the Jurassic: Permian limestones (including reef limestones), intermediate to basic volcanics and pyroclastics (green tuffs and agglomerates), of Lower Middle Triassic age are succeeded by Upper Triassic to Liassic dark-grey limestones with large pelecypods (Megalodontidae).

In the Jurassic, the deposits become more detrital: Upper Jurassic clastic series with coal lenses, clastic formations with large quartz pebbles in the Lower Cretaceous (similar to those in the Himalayas), rhythmic shale-limestone sequence of Upper Aptian age (Orbitolina sp.). On top of this sequence, red sandstones and siltstones (Takena formation<sup>1,2</sup>), intercalated with calc-alkaline volcanics and oyster-rich limestone beds, gradually become more and more continental upwards (lacustrine limestone and palaeosols). The Gangdise tonalites or granodiorites (Gangdise plutonic belt) and more recent granite bodies (Lhasa-Yangbajain granites) intrude the folded Mesozoic series which are unconformably overlain by red conglomerates with intercalations of purple volcanic tuffs and thick volcanics (Lingzizong formation 1.2). The volcanics (chiefly ignimbrites with dacites and andesites) cap most of the high mountains around Lhasa and north of the Linzhu basin and are probably of Palaeocene age  $^{1,2,18}$ .

The stratigraphy agrees well with the inference that the Lhasa block and its extensions to the west and east is a microcontinent

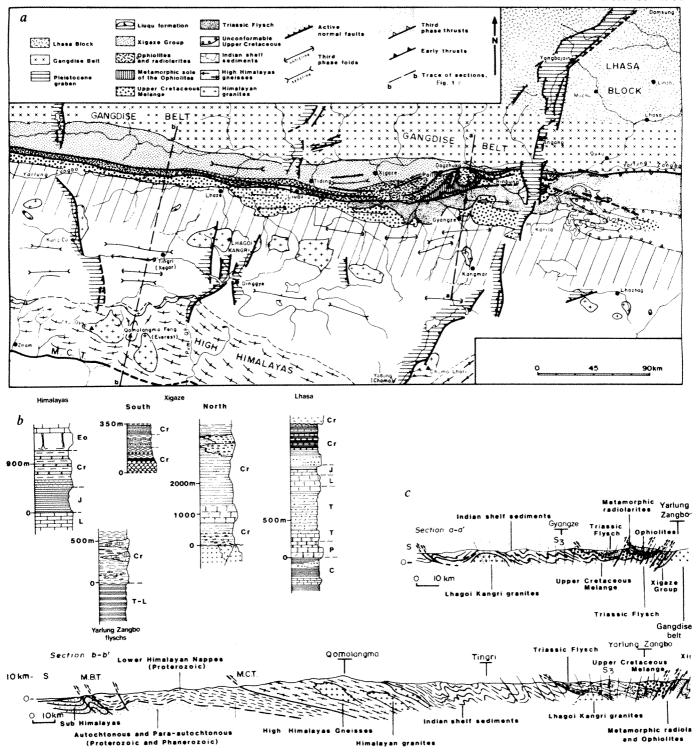

Fig. 1 a, Simplified structural map of southeastern Xizang (Tibet) and Himalayas (after ref. 2). Gangdise belt includes mostly granodiorites and granites but also volcanics (ignimbrites and andesites). Triassic flysch is present in the thinly dotted areas and at some places in the area with oblique bars. Oblique bars refer to sediments of the Indian continental slope which have suffered two phases of deformation and schistosities. The thrust contact between these formations and the more autochthonous Indian shelf sediments (one phase of deformation) is not clear everywhere and has not been represented. b, Stratigraphic columns of the main elements of southern Xizang (Tibet) (this study and ref. 2). Himalayan series (near Tingri): classical succession, from bottom to top: neritic limestones, Lower Jurassic; black shales and marls (Spiti formation), Upper Jurassic; sandstones (Giumal formation), Lower Cretaceous; thin bedded calcschists, with Globotruncanidae, Upper Cretaceous; without any unconformity, thick bedded limestones with abundant microfauna (Nummulites sp.), Tertiary (Palaeocene–Eocene). Zangbo flyschs: base of column is a flyschoid series, pelecypods (Daonella sp., Halobia sp.) give a Middle to Upper Triassic age. Top of column is wildflysch (sedimentary melange), with exotic blocks of various age (Upper Permian, Triassic, Cretaceous), lithology (limestones, cherts and radiolarites, pillow-lavas and so on) and size (cm to km). Globotruncanidae within the matrix give a Campanian (?) Maestrichtian age for this chaotic series which lies in stratigraphic unconformity on top of the Triassic-Jurassic (?) flysch. Xigaze group: south—sedimentary stratigraphic cover of the upper pillow-lavas of the ophiolites: red radiolarites and siliceous shales at the base, microfauna (radiolarians) indicate an Upper Albian, Lower Cenomanian (?) age. Rhythmic flyschoid series follow, with locally interbedded calcareous sandstones and coarse breccias (mass flows reworking lavas and cherts); north—the Xigaze group proper in s

of Gondwanian origin. In the Lower Mesozoic, it was separated from Laurasia by vast ocean basins, whose traces are to be found along the Kun-Lun, Bang Gong-Nu Jiang and other sutures within Central Tibet to the north 13,15. It probably detached from Gondwana in the Triassic or a little earlier<sup>22</sup>. Differences in the sedimentary environment north and south of the Zangbo progressively develop from the Triassic onwards. Until the Jurassic, the shallow marine sedimentary facies are still reminiscent of those on the northern margin of India. In contrast, after the Upper Jurassic, the sedimentary facies are more like those found elsewhere along the northern margin of Neo-Tethys, particularly in the Alpine Middle East. This is additional evidence for a large physical break between the Lhasa platform and the Gondwanian 'mainland' during part of the Upper Mesozoic. The most important tectonic deformations probably took place in the late Cretaceous before deposition of the thick upper volcanics.

# Oceanic crust and sedimentary cover along Yarlung Zangbo

Considerable work by Chinese geologists has drawn attention to the Yarlung Zangbo ophiolites  $^{1.13-15}$ . In the region near Xigaze, the ophiolites are particularly well exposed and form an eastwest belt  $\sim 170$  km long and 2-20 km wide (Fig. 1). Most of this belt was mapped during the summer of 1980 at a scale 1/100,000 and three of the largest massifs (Dagzhuka, Xigaze and Liuqu) have been the subject of particularly detailed structural studies (local maps at a scale of 1/25,000; ref. 16) and geochemical sampling.

On the whole, the ophiolites have not been much dismembered or weathered. Except for conjugate strike-slip faults trending ~N 60 °E and 110 °E within the massifs, the major faults are east-west thrusts of the ophiolites over the sedimentary series to the south. Displacements seem to have been a maximum for the Dagzhuka massif which forms a rather large thrust sheet on a sole of metamorphic rocks. Other massifs such as those near Tiding are made of stacked up thrust slices with some retrocharriage to the north onto the Xigaze group. The Xigaze, Liuqu and Polio massifs have merely been tilted ~60° to the north-west and display a remarkably complete and apparently continuous section. A typical cross-section is that of the Xigaze massif (Fig. 2). From north to south (and top to bottom), the southern rim of the Gangdise granodiorite 'batholith' is unconformably covered by variegated conglomerates and molasses representing locally the base of the Xigaze group. To the south the basal clastic sediments appear to grade into pelagic deposits which form the normal sedimentary cover of the oceanic crust<sup>19</sup>. Typically, a few metres of red radiolarian chert encrust the upper pillow-lavas. Above, the cherts give way to a rhythmic brown-green volcaniclastic formation, 300-400 m thick, with radiolaria-rich horizons at the base, of Upper Albian-Lower Cenomanian age.

The polarity of individual pillows (base to the south-east) is consistent with this description. The pillow-lavas are sometimes intercalated with lava flows several metres thick. Under the effusive volcanics, a peculiar succession of dolerite sills with some dyke swarms and exceptional screens of isotropic gabbro are observed. The dolerites, which form a real 'sill complex', are in contact with serpentinized dunites and harzburgites underneath. Further down (south), fresh peridotites consist mainly of harzburgites interbedded with Cr diopside-rich harzburgites. A shear zone of tectonized serpentine containing ophiolitic blocks, marks the basal thrust of the ophiolite complex on the red radiolarian cherts and coarse chert conglomerates.

If not disrupted by internal low angle shears that could have escaped our attention, the 'Xigaze' ophiolites represent a remarkable type of oceanic crust: the crust must have been thinner (at most 3.5 km thick) than the 'normal' crust (~5 km thick) found in many ophiolite complexes around the world. Also, whereas cumulate gabbros are abundant in typical ophiolites, they appear to be almost absent in the Xigaze complex (only small bodies, probably corresponding to magma chambers, have

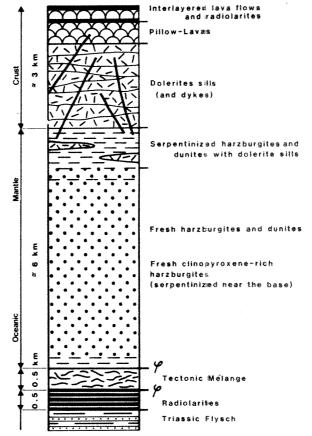

Fig. 2 Simplified section in the ophiolites of the Yarlung Zangbo Suture.

(For more details see accompanying article <sup>32</sup>.)

been observed in the vicinity of Dagzhuka and Tiding<sup>16</sup>). Finally the existence of Cr diopside-rich harzburgites at shallow depths under the crust is unusual: the ophiolitic oceanic mantle is normally composed of residual harzburgites and the occurrence of lherzolites is rare.

An important discovery is the apparent continuity between the normal pelagic cover of the ophiolites and the more clastic sediments which unconformably overlie the Gangdise granodiorites. This implies that the ophiolites of the Yarlung Zangbo suture zone correspond to the oceanic crust of a rather deep basin (the Xigaze basin), located south of the Trans-Himalayan region but at a short distance from it. Although the age of this basin is not accurately known, the radiolarian cherts above the pillows indicate that it must have formed before the Upper Albian. The main molassic units of the Xigaze group seem to have accumulated mostly during the Upper Aptian<sup>1,2</sup> but perhaps until the Upper Cretaceous and Lower Tertiary.

#### Triassic flysch and Cretaceous wildflysch

Between Lhozag in the east and Tingri to the west (Fig. 1), the Mesozoic sediments deposited on the north Indian margin are identical to those known as the 'Himalayan' series farther west<sup>27,28</sup> (Fig. 1): black shales ('Spiti') with nodules, of Upper Jurassic and Lower Cretaceous age, Lower Cretaceous sandstones and quartz pebbles conglomerates, Upper Cretaceous white limestones and mudstones with Globotruncana, and nummulitic limestones (Middle-Upper Eocene). There is no unconformity between the Upper Cretaceous and the Tertiary, which are merely separated by a hard ground in the mountains west of Tingri. Between the thick and monotonous deposits of the Indian margin and the ophiolites of the Zangbo suture, two distinct flysch formations of different ages and nature must be separated: the Triassic flysch and the Upper Cretaceous wildflysch or mélange.

The Daonella-bearing flysch is most likely to be of Triassic to Liassic age and slightly metamorphic (sericite). Facies of the rhythmic sediments appear to be quite similar to those of the Lamayuru flysch recognized in Ladakh<sup>22,27,28</sup>. On the other

hand, the mélange formation, which was long assimilated to the Triassic flysch, is not metamorphic and is best described as a dissociated wildflysch with exotic blocks. The blocks are of various sizes (from a few centimetres to a few kilometres), ages and facies and are sometimes more deformed than the matrix.

The most common elements are: Permian (Djulfian) whitegrey limestones with crinoids and foraminifera (Agathammina pusilla Geinitz, Geinitzina postcarbonica Spandel, Calcitornella heathi Cushman and Waters, Stipulina sp. Lys), Lower Triassic pink limestones (Meekoceras sp.) of 'Himalayan facies', Lower Jurassic (?) 'filament' limestones, Campanian-Maastrichtian limestones (Globotruncana), blocks made of a primary association of pillow-lavas and red or green micrites, grey, red or green cherts and grey chert breccia. Some blocks are composite: fragments of Permian, Triassic and Jurassic rocks are cemented by micritic limestones of Campanian-Maastrichtian age (Globotruncana stuarti or arca (Fig. 3). The largest (kilometre size) olistolithes are primarily formed of fossiliferous Permian limestones and marl limestone rhythmites or pelagic unmetamorphosed Triassic-Liassic flysch. The matrix is a rhythmic sediment with Globotruncana-bearing carbonate beds.

The wildflysch or mélange thus should be at least of uppermost Cretaceous age. Whereas the Triassic flysch probably corresponds to the accumulation prism along the passive northern margin of the Indian continent, the Cretaceous wildflysch undoubtedly formed in a more active tectonic environment, perhaps in the accretion prism of the subduction zone along the active margin of Asia.

# Overthrusting and shortening north of the Himalayas

In many places, the ophiolite belt along the Yarlung Zangbo seems to be limited to the north and south by steeply dipping faults. More detailed observations show that these faults correspond to rather minor and late tectonic events. The most important deformations and displacements have occurred during earlier phases responsible for the large scale overthrusting of the ophiolites to the south. Microtectonic studies permit the identification of four principal phases of shortening, the first and the third being the major ones.

The most intense deformations seem to have taken place during the first phase  $(\varphi_1)$ . They are best observed in the metamorphic sole under the ophiolites. Both the radiolarian cherts and associated pelagic limestones (marbles) and the schists with thin chert, sandstone and metatuff beds underneath show subhorizontal cleavage and a strong stretching lineation striking N 150° to N 180 °E. As the cleavage is parallel to the basal thrust, and the lineation parallel to the apparent direction of transport, the deformation and metamorphism probably occurred during overthrusting. The Triassic flysch is also affected by an early deformation phase with flattish flow cleavage and roughly north-south stretching lineation.

Fig. 3 Close-up of a Triassic block included in a primary Upper Cretaceous mudstone matrix; the whole is reworked as an exotic block in the late Cretaceous wildflysch (~20 km south of Xigaze).

Kilometric size folds overturned to the south or west can be related to this first phase.

The second tectonic phase  $(\varphi_2)$  is still characterized by north dipping thrusts. However, there seems to be no penetrative deformation and no metamorphism associated with this phase. The final effect is an exaggeration of the early overthrusts which brings the ophiolites, the metamorphic cherts and the Triassic flyschs onto the mélange and sometimes the autochthonous series of the continental slope of India.

The pronounced south vergence of the earliest tectonic events in the Yarlung Zangbo zone implies that some of the oceanic crust of the Tethyan Sea was subducted to the north under the Xigaze basin. The deformed cherts and pelagic slates now incorporated in the metamorphic sole of the ophiolites may represent scraped fragments of the late-Jurassic to mid-Cretaceous cover<sup>7</sup> of this crust. However, because the strong deformation linked with the large scale overthrusts also affects the Triassic flysch and the autochthonous series, and it is logical to relate most of the tectonics to the emplacement (obduction) of the ophiolites onto the northern margin of India.

Along the Yarlung Zangbo zone, the Upper Cretaceous mélange, the Triassic flysch and autochthonous Indian series, and the thrust contacts have been folded again by a third phase  $(\varphi_3)$ characterized by upright folds with undecided vergence and fan-shaped cleavage (S<sub>3</sub>) (Fig. 1). The third phase is especially clear in the region near Rinbung where it has produced retrocharriages: slices of ophiolites, radiolarian cherts and Triassic flysch have been emplaced onto the Xigaze group, along south dipping thrusts outlined by fragments of serpentine. In the series of the Indian margin, south of the granite batholiths of the Lhagoi Kangri range, the third phase is the only one to be observed in the Eocene (near Tingri). The intensity of the deformation and the asymmetry of the folds related to this phase increase towards the south into the lower units of the 'High Himalaya slab'. In the Cambro-Ordovician, the folds are clearly south vergent and the flow cleavage synchronous with metamorphism. Yet further down and south, ductile shear becomes predominant in the augen gneisses injected with tourmaline leucogranite sheets parallel to the foliation. The third phase is also essentially responsible for the deformation of the sediments of the Xigaze group whose uppermost units are perhaps of Eocene age. The style of folding is typical of late phases of rather symmetrical shortening: east-west folds, with steeply dipping cleavage (Fig. 4) are slightly south vergent in most of the basin (subvertical southern limbs). The vergence to the south is most pronounced near the southern edge whereas a north vergence appears locally near the Gangdise batholith

According to some of us (P.M., J.A., J.P.B. and M.B.) three independent sets of observations suggest that the early deformations synchronous with the emplacement of the ultrabasic thrust sheets  $(\varphi_1)$  have occurred before the deposition of the mélange<sup>20</sup>: (1) between Gyangze and Lhaze, the mélange or wildflysch overlies unconformably the Spiti series; (2) whereas two phases of deformation  $(\varphi_1$  and  $\varphi_3)$  are observed in the Spiti sediments, only one phase  $(\varphi_3)$ ? can be recognized in the mélange; (3) elements in the mélange have experienced metamorphic deformation (perhaps  $\varphi_1$ ) before their incorporation in the mélange's matrix which displays only  $\varphi_3$  style deformations.

The most recent structures that can be attributed to north-south shortening in southern Tibet are discrete reverse faults, dipping rather steeply to the north or south. In several places (near Tiding, for example), the faults clearly cut folds of the third phase, and thus belong to a distinct tectonic event, here referred to as phase four  $(\varphi_4)$ . This fourth phase is rather modest and does not manifest itself by distributed folding of the series. It is responsible for the accentuation of the retrocharriage of the ophiolites and cherts slices onto the Xigaze group, which obliterates in most places the root zone of the ultramafic nappes.

In the region of Lhasa, Yangbajain and Linzhu, north of the Gangdise granodiorites, the most prominent folding of the

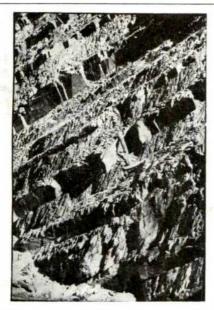

Fig. 4 Well developed steeply dipping slaty cleavage  $S_3$  in the Xigaze rhythmites, 1 km west of Tiding.

Mesozoic sediments, also with steeply dipping cleavage and undecided vergence, has occurred before the Palaeocene: precise  $^{40}$ Ar/ $^{39}$ Ar dating of the upper volcanics (Lingzizong formation) which lie unconformably on the folded continental Cretaceous red beds (Takena formation), but are not much deformed themselves, yielded an age of 60 Myr (ref. 18). The Lingzizong formation is only gently folded and broken by several steeply dipping east—west reverse faults, which can be attributed to the fourth phase of compression identified in the south. Perhaps the most prominent of these faults is that which bounds the Linzhu basin to the north: the fault clearly post-dates the Palaeocene ignimbrites and andesites of the Lingzizong formation which are offset several hundred metres.

Still later in the Tertiary, strike-slip faulting may have occurred, especially in the Zangbo suture zone. We found good microtectonic evidence for right lateral strike-slip faults, striking  $110^{\circ}-120^{\circ}$  N, south of Quxu. There, the suture appears to be more linear and vertical than in the region of Xigaze, a character often indicative of important strike-slip movements. The most recent deformations in Tibet, however, do not correspond to north-south shortening but, perhaps surprisingly, to east-west extension of the crust.

# Tibetan plateau extension during the Quaternary

Although some north-south faults in Tibet had already been described<sup>2,13</sup>, it was the Landsat images<sup>24,29</sup> that first suggested that normal faulting and active east-west extension was a dominant tectonic process over most of the plateau. This inference was supported by fault plane solutions of earthquakes. However, perhaps because extension seemed to contradict prevailing views on how the plateau formed<sup>26</sup>, many have been reluctant to accept it in the absence of more abundant and direct field evidence. We now have an ample collection of field observations<sup>17</sup> which demonstrate that recent distributed normal faulting is as important in southern Tibet as it is in regions such as the Aegean or the Basin and Range. The observations also show how Landsat photos can be used to study active tectonics.

Several normal fault systems cross our study area: from west to east, the most important ones are the Kung Co system, immediately north of Cho Oyu and Qomolangma Feng (Mt Everest) and the Yadong-Karila-Angang-Yangbajain-Damxung-Gulu system, which extends some 600 km from Chomo-Lhari to the south, to the region west of Amdo in the north (Fig. 1) (see also the accompanying paper 30). We were able to map in detail some segments of the Yadong-Gulu graben using aerial photographs 17.

The faults are especially clear in the morphology (Fig. 5). They cut moraines and post-glacial Quaternary terraces in many places (such as Angang, Damxung and Kung Co). In some places glacial valleys have been offset several hundreds of metres, which gives an order of magnitude for cumulated vertical movements since the end of the glaciation. Although most of the faults trend north-south, oblique faults cut or connect them. We found evidence for conjugate strike-slip motion along them.

Five clusters of recent surface breaks have been found west and north of Yangbajain. Uprooted bushes and disrupted turf suggest that most of these have been caused by earthquakes that occurred in the past few decades. The most ancient ones cannot be much older than a couple of centuries. All the breaks reactivate faults clearly visible on the satellite images. Particularly recent breaks are those which run along the western fault of the Gulu graben, south of Gulu, with  $\sim 3$  m of normal slip, and that found south of Lake Peng Co, with  $\sim 5$  m of right lateral strike-slip movement which we relate to the large earthquake of 18 November 1951 (M=8) (see accompanying paper  $^{30}$ ).

Many microtectonic measurements were taken in different favourable sites, either in 'basement' rocks near the master faults (Angang, Damxung and Kung Co) or within the Quaternary gravel beds of terraces (Yangbajain, Angang). Although the data are still being processed, preliminary results are consistent with a roughly east—west minimum principal stress  $(\sigma_3)$  and a vertical maximum principal stress  $(\sigma_1)$ . This stress state should rule out Quaternary folding or thrust faulting, for which we have found no field evidence.

Although no Quaternary volcanics were observed in the region we surveyed, hot springs were numerous and widespread. The rise of hot waters through the crust seems to be a direct consequence of east-west extension because the water often finds access to the surface through north-south cracks. This was particularly clear south of Kung Co, where travertine fissure systems have been mapped in detail.

#### Conclusion

The present field work has improved our knowledge of the geology and tectonic history of southern Tibet. Although it substantiates earlier conclusions 1,2,7,13-15,21,24, it also raises important questions and helps to define priorities for future field research.

It is now established that the Zangbo ophiolites are structurally attached to the Lhasa block and Gangdise calc-alkaline plutonic belt. This supports the idea that the Gangdise belt is the product of northwards subduction of the floor of Neotethys and that the Xigaze basin might have been a fore-arc basin? It is also likely that the 'Lhasa block' is a fragment of Gondwana, but when it became attached to Asia is unknown. For example, we do not know whether the Gangdise batholith was emplaced along an Andean margin, or along an island arc containing some continental fragments. Although great changes can occur along strike, the Ladakh-Kohistan batholith, which is the analogue of

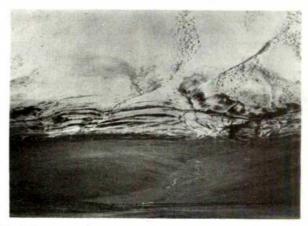

Fig. 5 Spectacular Quaternary scarps, outlined by snow, along the western master fault of the Gulu Graben (north-south trending faults).

the Gangdise batholith in the western Himalayas, has been interpreted as such an island arc in the Mesozoic<sup>3</sup>

The timing of tectonic deformations also raises problems. For instance, the age of emplacement of the Zangbo ophiolites onto the northern margin of the Indian continent is not yet well established. Some of us think it might have occurred earlier than at the end of the Eocene, which would place new constraints on speculations based on plate tectonic reconstructions.

Perhaps one of the most surprising observations was the comparatively small amount of shortening and deformation of the 'surface' sediments, north of the Zangbo ophiolites. Upright folds with steep cleavage predominate and no large-scale tangential tectonics seems to have occurred in the Upper Mesozoic series. Folding and deformation has been especially mila in the Tertiary series around Lhasa and farther north. This is in sharp contrast to the huge thrusts in the lower Himalayas,

or even typical amounts of shortening in other large orogenic belts and may be related to the flat topography of the Tibetan plateau over most of its surface. If such modest shortening in the Tertiary also prevails far north and west of the regions described here, India's northward push may have elevated Tibet in a different way than accordion shortening and thickening of the crust<sup>26</sup>

# Field evidence for active normal faulting in Tibet

P. Tapponnier\*, J. L. Mercier†, R. Armijo\*, Han Tonglin‡ & Zhou Ji‡

\* Institut de Physique du Globe, 4 place Jussieu, 75230 Paris Cédex 05, France † Université de Paris XI, Orsay, France ‡ Ministry of Geology, Beijing, China

Crustal thickening does not now occur in southern Tibet. Field observations made during the Chinese-French expedition of 1980 support an earlier hypothesis based on a combined analysis of satellite images and fault plane solutions of earthquakes. Immediately north of the highest peaks of the Himalayas, the tectonic regime is dominated by east-west extension. We have mapped a large number of north-south normal faults which sharply cut the glacial and post-glacial morphology, and followed several recent earthquake breaks along faults detected on satellite and aerial photographs. Microtectonic measurements in the Quaternary suggest that the maximum principal stress is vertical.

TECTONIC extension sometimes occurs far within continental regions, with no obvious connection with the world rift system and thus the causes are poorly understood. Of all these regions, Tibet is perhaps the most surprising. Since Argand presented his ideas on the tectonics of Asia<sup>1</sup> Tibet has emerged as a symbol of continental collision. Today, within the framework of plate tectonics, there is little doubt that the massive plateau, which maintains an elevation of some 4 km, over 1,000 km north of the Himalayas, is anything but a direct consequence of the most spectacular collision in the Cenozoic-that of India with Eurasia. However, the forces that have pushed up this immense region and somehow thickened its continental crust<sup>1-3</sup> do not thicken it appreciably now. Instead, the crust of Tibet is stretched in an east-west direction. The first field observations of the 1980 French-Chinese expedition firmly establish predictions made with satellite images and fault plane solutions of earthquakes4,5 and substantiate descriptions already made by Chinese geologists both from aerial photographs and in the field<sup>6</sup>. Here we summarize the most spectacular evidence for recent normal faulting and the ensuing preliminary conclusions.

#### Large normal fault systems of southeastern Tibet

As can be seen on Fig. 1, large normal faults cut across the middle reaches of the Yarlung Zangbo River. Figure 1 shows a refined version of earlier maps prepared from satellite images only<sup>5</sup>. Because our field survey was not exhaustive, the present document has also been based on a more detailed interpretation of enlarged and/or better quality Landsat images of the region. However, as we found good correspondence between faults previously recognized on the images and Quaternary faults that could actually be observed in the field, we believe that Fig. 1 represents fairly accurately the pattern of active tectonics in southeastern Tibet.

Between 86° and 91°E, the only area within the limits ascribed to the 1980 French-Chinese study, the normal faults group into three major systems, elongated in a roughly northsouth direction.

Along most of the length of the three rift systems one master fault on one side of the flat Quaternary floor is usually more

@ 1001 bt 10 To

Fig. 1 Map of active tectonics and seismicity of southeastern Xizang and surrounding regions. Earthquake epicentres are from the map of epicentres of strong shocks of China<sup>9,10</sup>. Sizes of circles correspond to magnitudes (small,  $6 \le M < 7$ ; intermediate,  $7 \le M < 8$ ; large,  $8 \le M$ ). Fault plane solution is from ref. 5.

prominent than the other. Sometimes, there is only one such fault, as may also be observed in Greece, western Turkey and the Basin and Range. In addition the faults are discontinuous along strike, often forming en échelon arrays. The most prominent of the three systems is located to the east (Figs 1 and 2a). It extends ~600 km from Yadong, at the foot of the Chomo Lhari range, across the Zangbo suture and the Gangdise granodiorites, all the way to the headwaters of the Nu Jiang (Salween river). Because it is close to Lhasa, and along a major communication axis, we studied it more closely than the others, especially in its central part between the Zangbo and Gulu (Fig. 2b). Abrupt elevation differences along the main faults are typically of the order of 2 km. The three highest peaks of the region are located along the uplifted shoulder of the rift: they rise to >7 km (for example, Mt Noijinkangsang, Mt Nyainqentanglha) (Fig. 1). To the west, the Pum Qu and Kung Co Fault systems (Figs 1 and 2c) were less accessible. In particular, it was not possible to reach regions north of the Zangbo, and the Pum Qu faults between Tingri and Dinggye were seen only during a 2-day reconnaissance trip. Nevertheless, preliminary observations confirmed that the faults are active. The two fault systems are quite different: whereas the faults near Kung Co form a long and linear half graben, those that cut the Pum Qu valley make a cluster of more or less parallel breaks whose continuity across the Zangbo suture zone with the faults that extend northwards to Gyaring Co is not well expressed in the topography.

#### Evidence for post-glacial faulting

In many places along all three 'graben' systems, post-glacial faulting offers spectacular sights. The most numerous and clear examples are found along the Yadong-Gulu 'graben'. We observed three types of morphological evidence.

(1) Quaternary slopes with their ridge and gully topography are sharply cut by the faults (Fig. 3a) along most of their lengths, with typical offsets of a few to a few tens of metres.

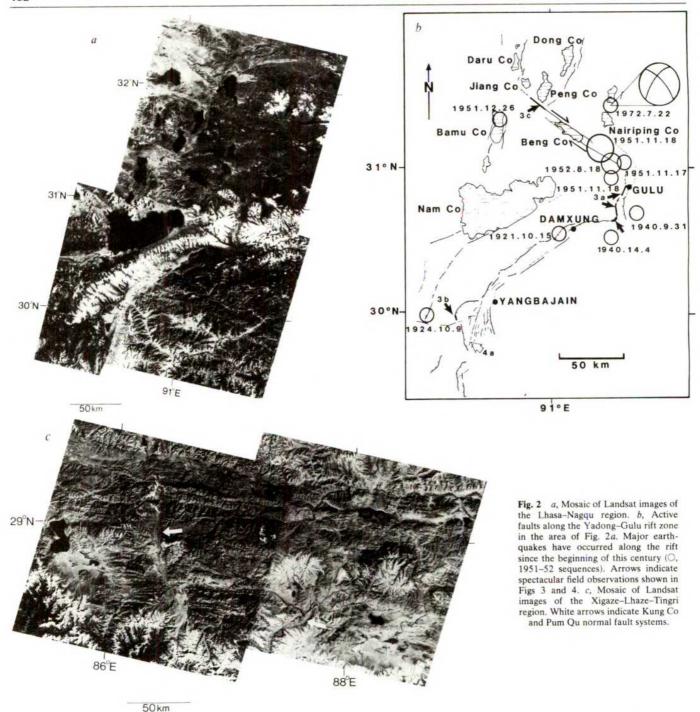

- (2) Near Damxung and Gulu (Fig. 1) attention is caught by several hanging fluvial valleys: ancient valley floors, or flat alluvial fans of tributaries are elevated several metres to a few tens of metres above the present day level of the Lhasa river valley.
- (3) West and north of Yangbajain, the same process, although presumably on a longer time scale, has produced perched glacial valleys (Fig. 3b). This is the most impressive effect of Quaternary normal faulting as valley floors and lateral moraines are sometimes offset as much as several hundred metres.

South-west of Yangbajain (Fig. 1), the Quaternary floor of the Yadong-Gulu 'graben' is cut by a remarkably large number of roughly north-south trending scarps, especially on its eastern side (Figs 1, 2b and 4a). The resulting rift in rift structure, with outward tilt of the Quaternary terraces, is reminiscent of regions of Afar or Iceland, if only because of the fault density. This area will be described in more detail elsewhere<sup>7.8</sup>.

Post-glacial normal faulting is also found along some of the other rifts. For example, spectacularly uplifted glacial valleys, also visible on the satellite images (Fig. 2c), testify for some 500 m of vertical displacement along the master fault near Kung Co, presumably in the past several thousand years. Clearly, more detailed and systematic studies of the post-glacial morphology will be useful for estimating recent extension rates in southern Tibet.

#### Historic surface breaks

Several surface breaks that can be attributed to recent earth-quakes were found along the Yadong-Gulu graben, between the Zangbo and Peng Co (Lake Peng) (Figs 2b, 3a, 3c). All of these reactivate faults that cut the Quaternary morphology, or are located near such faults. Typical vertical offsets are of the order of a few metres. The most recent breaks are observed west of Yangbajain, near Gulu, and near the southern tip of Peng Co: there, the disrupted vegetation has not grown back and the

corresponding earthquakes probably occurred in the past few decades. Epicentres on Figs 1 and 2b are from the historic catalogue of earthquakes compiled by the Institute of Geophysics of the Academia Sinica<sup>9,10</sup>. As for most of Western China, the catalogue contains only shocks which have occurred since the turn of the century, a fact that reflects the low density of population. In addition, we do not know the accuracy with which the epicentres are located, and this makes correlations with surface breaks difficult. Nevertheless, it is tempting to associate the freshest ground breaks near Gulu and Peng Co with the major earthquake sequence that shook the region in 1951–1952.

The sequence, the most important known to have taken place within the Tibetan plateau, was composed of one magnitude 8 shock, one magnitude 7 shock, and at least two shocks with magnitudes >6. All the epicentres cluster near the eastern extremity of a long and linear fault zone (Fig. 2a, b), which we will refer to as the Beng Co fault. This tectonic feature, particularly sharp on the satellite images, has been interpreted as a

predominantly strike-slip fault5,11. One of the major finds of a reconnaissance trip to the region of Peng Co, which was more easily accessible, was a straight alignment of pressure ridges and cracks (mole tracks) in the meadows immediately south of the lake (Fig. 3c). In two places, the rather fresh break, oriented  $\sim N$ 135° E, cut across Quaternary ground morphology and we could estimate a right lateral offset of at least 5 m. This supports the idea that the Beng Co fault is indeed essentially a right lateral strike-slip fault and that it was activated by the magnitude 8 earthquake of 1951. Although the epicentre is located near the eastern extremity of the fault, the break appears to have propagated at least 100 km to the west, to the place where we observed it. The main shock of the 1951-52 sequence would thus be strike-slip but it is not unlikely that foreshocks and aftershocks (Figs 1, 2b) have ruptured the normal faults of the Gulu graben, (Figs 2b, 3a). According to one of us (H.T.), the study of annual growth rings of trees on both sides of the normal fault south of Gulu supports the inference that this fault was activated in 1951-52.

Fig. 3 a, Quaternary normal fault near Gulu. The thin white line (white arrows) which runs along the main scarp probably corresponds to the surface break of one of the 1951–52 earthquakes. b, West of Yangbajain, glacial valley and moraines are cut by a prominent normal fault. c, Eroded mole tracks follow the straight surface break presumed to be that of the magnitude

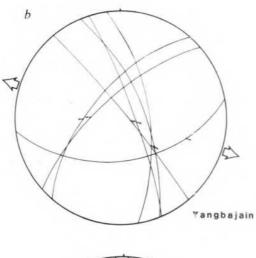

8 earthquake of 18 November 1951.

#### Geometry of faulting and stress in the crust

The observations above (Figs 1, 5) show that the present tectonic regime in southeastern Tibet is dominated by east—west extension. However, as was already suspected from the satellite images, this involves not only north—south trending normal faults, but also strike-slip faults, which sometimes provide the kinematic link between distinct normal fault systems, much as transform faults between ridge segments in the oceans. Such is the case for the Beng Co fault, and probably other faults with similar orientations (for example along Gyaring Co, Fig. 1). Faults with a 'conjugate' strike (N 60° E) also exist and we found good evidence for left lateral movements along them (see Fig. 1, near Yangbajain and Damxung). In addition, the *en échelon* geometry of some normal fault systems (Fig. 1) favour strike-slip components in the deformation of the crust.

These kinematics are born out by our microtectonic measurements either in the Quaternary (Fig. 4a) or in the fractured bedrock and mylonites near the main faults. Although these measurements and the inferences from them will be reported in detail elsewhere<sup>8</sup>, a sample diagram is shown in Fig. 4b. Orientations of the faults are variable, and the corresponding slip on them entails a variable strike-slip component. Nevertheless, all faults have a large normal component and are compatible only with extensional tectonics. Nowhere did we observe reverse faulting or folding in the Quaternary. The extension direction can change from one site to the next, but it is east—west on average. Numerical inversion of the microtectonic data (slickensides)<sup>12</sup> is consistent with a vertical maximum principal stress  $(\sigma_1)$  and a roughly east—west minimum principal stress  $(\sigma_3)$  (ref. 8).

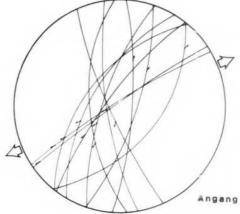

Fig. 4 a, South of Yangbajain: normal fault cutting Quaternary terrace gravels. Many other normal faults occur nearby. b, Measurements of slickensides (arrows) on Quaternary faults (great circles) in the regions of Angang and Yangbajain (lower hemisphere projection) indicate soughly east-west extension.

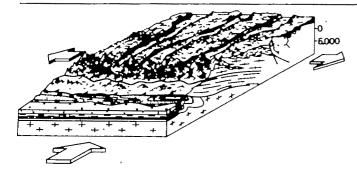

Fig. 5 Idealized block diagram shows how, whereas folding and shortening of the crust still occurs in the Sawaliks and lower Himalayas in response to the northward penetration of India into Asia, east-west extension now predominates on the high Tibetan plateau

#### Conclusions

Although north-south shortening of the crust is evidenced by upright folds and cleavage in early to middle Cretaceous sediments and much more gentle folding in late Cretaceous and early Tertiary sediments 6,13,14, shortening has apparently not been a dominant process in the late Cenozoic tectonics of southern Tibet. During the upper Quaternary at least, but perhaps for a longer period of time, east-west extension must have prevailed on the Tibetan plateau. North-south normal faulting has been especially active in the past several thousand years. As in other areas such as the Aegean in the Mediterranean, or the Basin and Range in North America, such faulting appears to be distributed over a wide area.

The faults are perpendicular not only to the Himalayan belt in which they stop rather abruptly, but to most of the more ancient Mesozoic and Tertiary fold trends and roughly east-west structural and palaeogeographical zones within the plateau. In particular, the fault systems cut through major sutures such as the Yarlung Zangbo. Thus, although deviation by more ancient structural trends is possible (Fig. 1), a large proportion of the north-south normal faults are probably not reactivated older ones as has often been suggested 15. Hence, perhaps more than in any other region, extension in Tibet seems to reflect a particular state of stress in the crust and upper mantle, where gravity can be the main driving force. Microtectonic observations made during the Chinese-French expedition support this inference.

Although further speculations on the cause of the east-west extension must await a better knowledge of the upper mantle and crustal structure of Tibet, the approximately double thickness of the continental crust as well as the softness of the hot lower crust<sup>16</sup> probably favour east—west flow in response to India's northward push<sup>5,17</sup>.

Now that widespread normal faulting on the Tibetan plateau can be considered more firmly established, important questions remain for future field work: when did incipient extension take over folding and crustal thickening? Does the time when this change occurred compare with the time when Tibet acquired its abnormally high elevation? At what rates has east-west stretching of the crust taken place since then?

New data on these questions will surely place constraints on how large and high plateaus form and evolve during continental collision.

# The Xigaze ophiolite (Tibet): a peculiar oceanic lithosphere

A. Nicolas\*, J. Girardeaut, J. Marcouxt, B. Dupret, Wang Xibins, Cao Yougongs, Zheng Haixiangs & Xiao Xuchangs

\* Laboratoire de Tectonophysique, 38 boulevard Michelet, 44072 Nantes Cédex, France † Institut de Physique du Globe, 4 place Jussieu, 75230 Paris Cédex 05, France ‡ Laboratoire de Géologie, Faculté des Sciences, Moulin de la House, BP 347, 51062 Reims, France Institute of Geology, Chinese Academy of Geological Sciences, Beijing, China

The Xigaze ophiolite which outcrops along the Yarlung Zangbo river, southern Tibet, locally displays a complete ophiolitic sequence from marine sedimentary cover over basaltic volcanics to the north, to fresh Cr diopside-rich harzburgites to the south. In contrast with other ophiolites, the mafic part of the sequence is particularly thin. It is almost devoid of cumulate gabbros consisting of a diabase sill complex covered by lava-flows or pillow-lavas. The ultramafic unit is poor in residual harzburgites and dunites and consists dominantly of fresh Cr diopside-rich harzburgites. The origin of this peculiar ophiolite (of oceanic crust) is discussed.

OPHIOLITE complexes in various parts of the world display remarkably comparable sections with, from top to bottom, basaltic lavas, dolerite dykes, isotropic gabbros, cumulate gabbros and ultramafic rocks, resting on tectonic dunites and harzburgites. The mafic part of these complexes usually represents a thickness of between 3 and 6 km (refs 1,2). It is this remarkable homogeneity, at least in their gross features, which led to the concept of ophiolites and to its informal definition3. In contrast to this homogeneity, various oceanic environments have been considered as potential sites for the origin of ophiolites: oceanic ridges with various spreading rates<sup>4-10</sup>, back-arc basins<sup>11,12</sup>, ridges with various spreading rates<sup>4–10</sup>, back-arc basins<sup>11,12</sup>, island arcs<sup>13,14</sup> and even transform faults<sup>15</sup>. The Xigaze ophiolite outcrops in Thet aleast the T. outcrops in Tibet along the Indus-Zangbo suture zone, one of many sutures which separate the Indian continent from the northern plate(s). Only limited data are available about these ophiolites 1,10 although they have been discussed in a recent report16 that draws attention to the presence of limited amounts of cumulate gabbros and suggests that they may well correspond

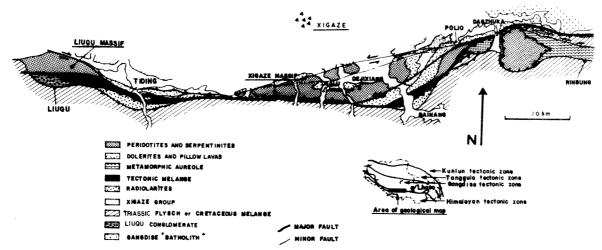

Fig. 1 Geological map of the Yarlung Zangbo ophiolite belt around Xigaze.

to a slow-spreading ridge on the evidence of a "thin, perhaps discontinuous plutonic sequence".

Considering that, as far as we know, ophiolites without cumulate gabbros have been identified only in highly dismembered massifs, the detailed structural study of the Xigaze ophiolite was of particular interest. It should contribute to the discussion on the relation between the existence of magma chambers in the oceanic crust beneath spreading centres and the problems of rate of partial melting in the mantle and rate of oceanic expansion.

#### The Xigaze ophiolite

The Indus-Zangbo suture in Tibet is commonly marked by a discontinuous line of serpentinites or by minor ophiolite bodies. The Xigaze ophiolite belt is >170 km long in the east-west direction of the suture and has a maximum width of 20 km (Fig. 1). It contains three areas where large masses of ultramafic and mafic rocks have been preserved from the intense deformations observed elsewhere along the suture zone: the Dagzhuka, the Xigaze and the Liuqu massifs. In the Dagzhuka and Xigaze massifs, a sequence from sedimentary cover over basaltic volcanics to the north to fresh harzburgites rich in Cr diopside to the south has been identified. Together with more partial sections such as those of Dejixiang, Polio and Tiding they enable a schematic cross-section to be constructed for the Xigaze ophiolite (Fig. 2).

Due to collision along the Indus-Zangbo suture zone, the ophiolites in the Xigaze area have been tilted into a 060°, 60°NW attitude with only local variations. As a result, the top of the sequence and its sedimentary cover are located to the north of the section. Generally, the main lithological contacts in the ophiolite, oriented at 060°, 60°NW, are few tectonized. They contrast with the east-west contacts, the main one being the southern limit of the ophiolite, which cut the former and are systematically tectonic.

From north to south (Fig. 2) one first meets the Gangdise 'batholith' which is commonly ascribed to an island arc or a continental active margin environment<sup>13,18</sup>. Its location relative to the suture, its east—west orientation and its lithologies point to the presence of an underlying, northward subduction zone. The northern part of the Xigaze group is considered as an essentially detrital formation accumulated on the southern margin of the granodiorite (Gangdise) massif. Its contact with the ophiolite often is a stratigraphic one with a few metres of cherts over the basaltic volcanics, covered by marine pelagic sediments reworking in various proportions the underlying volcanics<sup>19</sup>.

Below the cherts either pillow-lavas or lava-flows are observed (Fig. 3). They are parallel to the chert orientation with local departures in the pillow-lavas. The polarity in the pillow-lavas is always with the top northward. Their diameter in section is smaller than 60-80 cm and they are often extended in tubes with no particular directions. They are either largely variolitic,

with 1-cm varioles or massive with only a finer grain rim. Their matrix is not abundant and exclusively constituted by volcanic debris and glass. Beneath a few hundred metres of volcanics, the first diabase dykes and sills appear. They typically present chilled margins and have been observed cutting through the pillows. They progressively become more abundant until they constitute a sill complex with sills intrusive into sills. The sill rather than dyke nature is deduced from their general parallelism with the overlying volcanic lava-flows and sediments. A few dykes, normal to the sills, are often present (Fig. 3); these can be very abundant in some massifs such as Dagzhuka. The thickness of individual sills is in the metre range. When they reach a few metres, microgabbro textures can be obtained in their core. New sills intrusive in such rocks can create the illusion that they are intrusive in a fine-grained gabbroic formation. True plutonic rocks are uncommon between diabase sills with the exception of a few isotropic gabbros and trondjhemite screens.

In the Dagzhuka and Tiding massifs (Fig. 1), small bodies of cumulate gabbros and ultramafic rocks are lecally present at the base of this sill complex. In these massifs, the thickness of the cumulate olivine gabbros is <170 m and <120 m respectively. In the Dagzhuka massif, the walls of the chambers are made of troctolites and dunites which can be intempreted as the first cumulates or, alternatively, as residual wells impregnated by feldspar coming from the chamber. The shape of the magma chambers is very irregular and, in Dagzhuka, the total thickness mentioned above could be achieved by addition of smaller chambers. In Tiding, there is a remarkably thick sequence of isotropic gabbros which may represent the upper part of a comparatively large magma chamber.

The thickness of this crustal unit does not exceed 3 km. It lies over a serpentinized harzburgite and dunite formation penetrated by numerous diabase sills. Those sills which can constitute 50% in volume of this new formation are often particularly thick, up to 7 m. They have been observed to branch to perpendicular dykes which probably represent their feeders. A few rodingitized gabbro dykes also intrude the ultramafic rocks but they are cut by the diabase ones. In contrast with the gabbros, the diabase dykes seem to be usually fresh or rodingitized only along their margins. As rodingitization probably accompanies the serpentinization of the periidotite20, it can be concluded that the gabbro dykes were emplaced before the serpentinization and the diabase ones, after itsor late during the process. The peridotite structure is not altered by the serpentinization except locally where low-temperature deformations have disrupted and boundinaged the dykes and developed a slickenside cleavage in the serpentinites. As a consequence the coarse porphyroclastic texture of the peridotite, typical of hightemperature flow<sup>22</sup> is still visible and its orientation can be mapped. The foliation is represented with its field orientation in Fig. 2 and with its restored orientation in Fig. 3. The thickness of

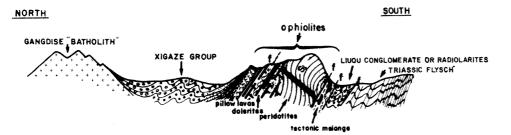

Fig. 2 Schematic north-south crosssection through the Yarlung Zangbo suture near Xigaze. S<sub>1</sub>, foliation.

this harzburgite and dunite formation containing the sills is 500 m on average with important local variations. Downwards it grades into a 500-m unit formed of serpentinized foliated harzburgites and dunites with a decreasing amount of gabbro and diabase dykes. The degree of serpentinization rapidly decreases in these peridotites. After 1-2 km of relatively fresh harzburgites and dunites, fresh harzburgites with a crude layering resulting from the alternation of Cr diopside-rich and Cr diopside-poor facies, visible at various scales are encountered. No banding is observed in these rocks except for a few pyroxenites. The rocks are well foliated with discordant shear zones represented by a few metres of mylonitic peridotites in the Xigaze and Liuqu massifs (Figs 2, 3). Outside these bands, fine to coarse-grained porphyroclastic structures related to hightemperature plastic flow are observed. At the massif scale, the tectonic structures display a relatively irregular pattern though remaining consistent from one massif to another1

The southern east-west contact of the Xigaze ophiolite with the sedimentary formations is tectonic. Over 500-800 m, the ultramafic rocks are transformed into an ophiolitic mélange with blocks of rodingitized gabbros and diabases floating in a schistose serpentinite. On the other side of this major tectonic contact, either radiolarites or a coarse red conglomerate separate the ophiolites from the Triassic flysch series. They are also strongly deformed and schistozed at the contact but, like the serpentinites, are devoid of any metamorphism.

Amphibolites, garnet amphibolites and quartzites have been observed in several localities (Liuqu, Bainang and Dagzhuka) as inclusions in the serpentinite mélange. In the Dagzhuka massif, mylonitic peridotites are developed over several dozen metres above the basal contact which contains blocks of amphibolites in a serpentinite matrix. Beneath, a metamorphic formation consisting of quartzites, phyllites and locally ophicalcites, outcrops over 300 m. This might represent the basal part of the metamorphic aureole well known in many ophiolites<sup>22,23</sup>.

#### Discussion

Considering the general tectonic situation, special attention must be devoted to the question of continuity within the ophiolites mainly at the critical level between the mafic and ultramafic formations. This continuity is thought to be locally preserved for the following reasons.

First, the sills and the dykes are remarkably continuous, keeping the same attitude from the volcanics down to the upper peridotites; and second, the same general sequence is systematically observed along the area studied (Fig. 1). In particular, the possibility of a squeezing out of the gabbros is remote, considering that no large masses of gabbros have been found. On the other hand, isolated pockets of gabbros are now well identified within the mafic part of the sequence. We thus think that the gabbros have not been faulted out and that a continuous section was observed in the Xigaze area.

The specific characters of the Xigaze ophiolite can be summarized as follows:

(1) In contrast with other non-dismembered ophiolites, the mafic part of the sequence is nearly devoid of plutonic rocks except for the small cumulate gabbro bodies found in the Dagzhuka and Tiding massifs. The mafic formation is entirely comprised of basaltic volcanics overlying diabases and dolerites with isotropic gabbro screens and, more rarely, trondjhemite screens.

- (2) The diabase unit is a sill complex and not a dyke complex, as expected, with sills intrusive one into the other and only a few branching dykes at right angles to the sills. This has not yet been described in ophiolites except in the Point Sal ophiolite<sup>24</sup>.
- (3) This mafic part of the sequence is remarkably thin (compared with that measured in non-dismembered ophiolites) with local variations in thickness, but does not exceed 3 km.
- (4) The upper harzburgites and dunites are invaded by thick diabase sills over a thickness of  $\sim 1$  km. To our knowledge, this is also unique as diabase dykes are very scarce in the few ophiolite massifs where they have been described cross-cutting the harzburgites<sup>25</sup>.
- (5) Cr diopside-rich harzburgites are abundant in the ultramafic unit and appear only at 2 km beneath the mafic unit and at 5 km beneath the sedimentary cover of the ophiolite sequence. This is unique as the ultramafic unit in ophiolites is usually composed of depleted harzburgites with  $Cr_2$  diopside-rich harzburgites appearing only in the basal section in a few massifs<sup>27</sup>.
- (6) Local thin shear zones inside the ultramafics with low-temperature plastic flow structures have not been described in ophiolites. Those observed are generally located at the base of the ultramafics. They are thicker and clearly related to late thrusting of the lithosphere<sup>28</sup>.

Depending on the spreading rate, the structural, petrological and geochemical character of oceanic spreading centres are expected to vary. The difference seems to be essentially controlled by the heat budget<sup>29,30</sup>. Slow-spreading ridges will have a lower rate of magma generation and therefore of heat production for a comparable thermal dissipation rate. As a

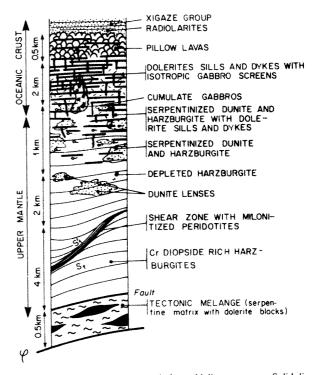

Fig. 3 Schematic cross-section of the ophiolite sequence. Solid lines represent the foliation S<sub>1</sub>. The smaller the spacing, the higher the strain. The various attitudes have been restored after a rotation to horizontal of the radiolarites and basalt flows.

result, magma chambers where the gabbro cumulate sequence crystallizes are not expected for spreading rates of <1 cm yr (refs 31, 32). Steeper isotherms in the mantle should tend to concentrate the magmatic and tectonic activity closer to the ridge than in fast-spreading ridges. However, as mentioned elsewhere<sup>33</sup>, one of the bases for these thermal models is that the upwelling rate of the asthenosphere is proportional to the rate of spreading. The fact that spreading is a discontinuous phenomenon is likely to change these conclusions.

If these conclusions are applied to the Xigaze ophiolite, our evidence indicates a crust formed at a spreading centre with a particularly slow spreading rate, <1 cm yr<sup>-1</sup> if one accepts this limit for the transition from continuous to discontinuous magma chambers. This interpretation differs significantly from that of Wu Haoruo and Deng Wanning14 who think—based on major element chemistry—that the Xigaze ophiolite has been formed in a subduction zone environment. Further detailed geochemical studies are necessary, however, as most of the studied mafic rocks are altered.

Although the mafic crust in our case is only  $\leq 3$  km on average. the geophysical Moho would be deeper, considering that the 1-2 km of serpentinized peridotites with up to 50% in volume of diabase sills display crustal seismic velocities. Our evidence that serpentinization occurred before the diabase emplacement shows that these peridotites were serpentinized at the ridge itself and therefore that they belong geophysically to the crust. The 'geophysical crust' would therefore have a thickness comparable with that determined by a  $V_p$  transition from  $6.8 \,\mathrm{km \, s^{-1}}$  to 8.1 km s<sup>-1</sup> for slow ridges like the Atlantic one<sup>3</sup>

Finally, if the interpretation that the Xigaze ophiolite originated at a slow ridge is correct, the study of its structure, petrology and geochemistry bears directly on the structure and nature of slow ridges. In this respect, the occurrence of a sill complex as the main component of the crust, which also extends in the uppermost mantle, is interesting.

Antibodies which are specific to the Z-DNA conformation have been purified and characterized on the basis of their binding to three different DNA polymers which can form this left-handed helix. These antibodies bind specifically to polytene chromosomes of Drosophila melanogaster as visualized by fluorescent staining. The staining is found in the interband regions and its intensity varies among different interbands in a reproducible manner. This is the first identification of the Z-DNA conformation in material of biological origin.

LEFT-HANDED double-stranded DNA was first discovered by an atomic resolution X-ray crystallographic analysis of the hexanucleoside pentaphosphate CpGpCpGpCpG (ref. 1). In this conformation the DNA formed a double helix with Watson-Crick base pairs and antiparallel sugar-phosphate chains; the sugar-phosphate backbone followed a zig-zag course and for this reason was named Z-DNA. In Z-DNA the guanine bases have rotated about the glycosydic bond and have assumed a syn conformation, in contrast to the anti conformation in B-DNA. The early observation by Pohl and Jovin<sup>2</sup> of salt-induced inversion of the circular dichroism spectrum of poly(dG-dC)

DNA in 4 M NaCl solution can now be understood as the conformational transition of the right-handed B-DNA to the left-handed Z-DNA<sup>3,4</sup>. Z-DNA has been seen in several crystal structure and fibre analyses<sup>5-8</sup> and generally, DNA with alternating purine-pyrimidine sequences may be expected to have Z-forming potential.

We have recently demonstrated that left-handed Z-DNA is a strong immunogen; in both rabbits and mice antibodies can be raised which are specific for the left-handed Z conformation and will not react with right-handed B-DNA9. Because of their specificity, antibodies can be used to determine the distribution of Z-DNA in biological systems. Here we have purified antibodies to Z-DNA from rabbit sera and demonstrate their specificity for the left-handed Z conformation. We have used these antibodies for indirect immunofluorescent staining of Drosophila melanogaster polytene chromosomes. Because a large polytene chromosome can consist of a thousand or more individual chromatids in very precise alignment, these chromosomes provide a magnification that cannot be obtained with other types of chromosomes. In addition, polytene chromosomes are interphase chromosomes, active in both transcription and replication, in spite of the relatively condensed state of the chromatin. The alignment of the many chromatids making up a polytene chromosome is so precise that regions of tight coiling in the individual chromatids match up to give the appearance of bands across the width of each chromosome. These bands are separated by interbands in which the chromatid fibres are relatively extended. The banding pattern of each

chromosome is essentially constant from nucleus to nucleus and from individual to individual, and must thus reflect basic features of chromatid structure, although the significance of this structure is not understood. Polytene chromosomes therefore provide a unique opportunity for studying the conformational states of specific chromatin regions at times when the chromatin is genetically active.

Indirect immunofluorescence has been widely used to study the distribution of proteins on polytene chromosomes<sup>10</sup>, and here we apply this technique to investigate the occurrence and distribution of Z-DNA in these chromosomes. We show that anti-Z-DNA antibodies bind to polytene chromosomes in a very reproducible pattern, exhibiting fluorescence staining exclusively in interband regions in our experimental conditions. This finding may throw some light on the role of Z-DNA in biological systems and may lead to some clues concerning the significance of banding in eukaryotic chromosomes.

#### Characterization of the antibody

As described earlier<sup>9</sup>, the anti-Z-DNA antibodies were raised by injecting rabbits with brominated poly(dG-dC)·poly(dG-dC). This DNA polymer remains in the Z-form even in low salt because most of the bromine atoms are on the C-8 position of guanine, stabilizing guanine in the *syn* conformation. In low salt, non-brominated poly(dG-dC)·poly(dG-dC) is in the B conformation and does not react with the antibody. In 4 M NaCl the unmodified poly(dG-dC)·poly(dG-dC) is converted to the Z form and does react with the anti-Z-DNA antibody.

Although our initial experiments on polytene chromosomes were carried out with whole sera from rabbits injected with brominated poly(dG-dC)·poly(dG-dC), the more recent experiments have been done with antibodies purified from these sera. The purified antibody was obtained by preparative scale quantitative immunoprecipitation in 4 M NaCl using unmodified poly(dG-dC)·poly(dG-dC), which is in the Z conformation at that salt concentration<sup>2,4</sup>. The specificity of the affinity-purified antibody for the Z conformation was tested on native *Escherichia coli* DNA and three different polymers, poly(dG-dC)·poly(dG-dC), brominated poly(dG-dC)·poly(dG-dC)·poly(dG-dC) and the methylated polymer poly(dG-dC)·

Fig. 1 Specificity of the affinity-purified anti-Z-DNA antibody as measured by direct binding to <sup>3</sup>H-brominated poly(dG-dC) poly(dG-dC) (①), <sup>3</sup>H-poly(dG-m<sup>5</sup>dC) poly(dG-m<sup>5</sup>dC) (△), <sup>3</sup>H-poly(dG-dC) poly(dG-dC) dC) (O) and <sup>3</sup>H-labelled E. coli DNA (A) in 0.2 M NaCl (a), 1.5 M NaCl (b) and 4.0 M NaCl (c). The affinity-purified antibody was prepared by a modification of the procedure of Kitagawa and Okuhara<sup>22</sup>. A sample of rabbit serum was incubated with an equivalent amount of poly(dGdC) · poly(dG-dC) (as determined from quantitative precipitation curves) in 60 mM sodium phosphate, 30 mM EDTA, 4 M sodium chloride, pH 8.0, for 3 h at 37 °C and overnight at 4 °C. For equivalent proportions of antigen and antibody,  $75 A_{260}$  units of polynucleotide were added to 15 ml of serum. Resulting precipitates were washed three times with cold PBS (10 mM sodium phosphate, 140 mM sodium chloride, pH 7.4) and dissolved in 20 mM sodium carbonate, 5% dimethyl sulphoxide (DMSO) pH 10.5. The dissolved antibodies and antigen were separated on a DEAE-cellulose column (20 ml) previously equilibrated with 20 mM sodium carbonate, 5% DMSO, pH 10.5. The free antibody flowed through on washing with 20 mM sodium carbonate, 5% DMSO, pH 10.5. The retained nucleic acid was eluted by 20 mM sodium carbonate, 5% DMSO, 1 M NaCl, pH 10.5. The purified antibodies were dialysed against PBS and protein concentration determined by the method of Lowry et al.<sup>23</sup>. Radioimmunoassays (RIAs) were performed by incubating  $100\,\mu l$  samples of purified antibody serially diluted into the RIA buffer (60 mM sodium phosphate, 30 mM sodium EDTA, pH 8.0) containing 0.2 M NaCl (a), 1.5 M NaCl (b) or 4.0 M NaCl (c) with 100 ng of <sup>3</sup>H-labelled nucleic acid in 0.05 ml of the RIA buffer containing the indicated NaCl concentration for 1 h at room temperature. Then 0.05 ml of the y-globulin fraction of goat anti-rabbit immunoglobulin serum in PBS was added and the mixture kept at room temperature for an additional hour. The resulting precipitate was centrifuged, washed twice with RIA buffer containing the indicated NaCl concentration, dissolved in 1 ml 0.1 N NaOH and counted in 10 ml of Aquasol-2 (NEN). 3H-thymidinelabelled E. coli DNA was prepared from a mutant strain B3, as described previously<sup>24</sup>, but with a pulse of 0.5 mCi of <sup>3</sup>H-thymidine. <sup>3</sup>H-labelled poly(dG-m<sup>5</sup>dC) poly(dG-m<sup>5</sup>dC) was synthesized according to Behe and Felsenfeld<sup>11</sup>, except that 0.065 mCi of <sup>3</sup>H-dGTP (Amersham) was included into the synthesis reaction mixture. The other polymers were radiolabelled by nick translation<sup>25</sup>.

poly(dG-m<sup>5</sup>dC). Behe and Felsenfeld have shown that methylation on the 5 position of cytosine yields a polymer that is converted to Z-DNA at low concentrations of MgCl<sub>2</sub>, and has a midpoint for conversion by NaCl at 700 mM (ref. 11).

Figure 1 demonstrates the specificity of the purified antibody by showing its direct binding as a function of antibody concentration in three different salt environments using the four polymers. In 0.2 M NaCl, the antibody bound only the brominated poly(dG-dC) · poly(dG-dC) (Fig. 1a), the only one which has the Z conformation in 0.2 M NaCl. At 1.5 M NaCl, antibody bound the brominated and methylated polymers, both of which have the Z conformation, but not the two polymers which are in the B conformation at that ionic strength (Fig. 1b). In 4 M NaCl the brominated. methylated and unmodified dC) poly(dG-dC) were bound, but E. coli DNA was not (Fig. 1c). Poly(dG-dC) poly(dG-dC) is completely in the Z-DNA conformation in 4 M NaCl, where its Raman spectrum is identical with that of Z-DNA crystals4. The three experiments shown in Fig. 1 strikingly illustrate the effect of antigen conformation on the reactivity of the antibody. Only when the polymers are in the Z conformation does the affinity-purified antibody combine with the DNA antigen. When the antigen is not in the Z conformation, no reaction occurs. The same results were obtained with whole serum.

Further analyses on the specificity of the antibody were done by competitive radioimmunoassays in which the ability of other polymers to inhibit the binding of the antibody to a known form of Z-DNA was measured. No inhibition was seen with poly(dG), brominated poly(dG), poly(dG) poly(dC), brominated poly(dG), native and denatured calf thymus DNA, Vero RNA, DNA-RNA hybrids or double-stranded RNAs. All our experiments indicate that the antibody is highly specific for Z-DNA and does not recognize B-DNA or other nucleic acid conformations.

# Binding of antibodies to polytene chromosomes

Identical results were obtained when either the antibodies in whole serum or the affinity-purified antibodies were used to look for the presence of Z-DNA in polytene chromosomes from larval salivary glands of *D. melanogaster*. Antibodies bound to the chromosome are detected by the binding of a second antibody, a fluorescein-labelled goat antibody to the rabbit immunoglobulin. The second antibody also provides an amplification of the binding of the primary antibody, as several molecules of the goat antibody can bind to each rabbit antibody.

The anti-Z-DNA antibody stains the polytene chromosomes in a very distinct and specific way (Fig. 2a). It can be seen that there are many fluorescent regions on all the chromosome arms as well as a somewhat diminished and diffused staining in the chromocentre, where the arms are joined. All the control experiments described above have indicated that the antibody is recognizing the Z conformation. Other control experiments indicate that the antibody binding to the polytene chromosomes is also the antibody that recognizes the Z conformation (Fig. 2b,c). For the preparation shown in Fig. 2b the antibody was incubated with B-DNA, in the form of poly(dG-dC) poly(dGdC), before it was put on the chromosome preparation. The antibody staining of the chromosomes is not affected. However, when the antibody was preincubated with Z-DNA in the form of brominated poly(dG-dC) · poly(dG-dC), the chromosomal staining is completely abolished (Fig. 2c), and chromosomes appear uniformly dark. Note that preparations stained with antibody preincubated with Z-DNA reproducibly show more background fluorescence than do other preparations. This is because the antigen-antibody complex has precipitated throughout the field and around the outside of the chromosomes. This complex has not been washed away and has thus reacted with the fluorescent goat anti-rabbit antibody. Experiments in which the antibody was preincubated with either

native or denatured DNA from *Drosophila* embryos showed no effect on chromosomal staining.

The same chromosomal staining pattern is produced by whole serum from rabbits injected with brominated poly(dGdC) poly(dG-dC), by antibodies affinity purified from this serum by the brominated polymer in low salt, or by antibodies affinity purified from the serum by unmodified poly(dGdC) poly(dG-dC) in high salt where this polymer is in the Z conformation. We have also studied an antibody obtained from a rabbit injected with unmodified poly(dG-dC) poly(dG-dC), which exists as B-DNA in physiological salt solution. The antibody produced by this rabbit was of lower titre but was specific for Z-DNA at the dilution used in the experiment. To obtain this antibody, the polymer was injected into the rabbit complexed with methylated bovine serum albumin and it is assumed that the cationic charges on the surface of the methylated bovine serum albumin provided regions which converted local domains of the poly(dG-dC) · poly(dG-dC) into Z-DNA9. This last antibody produced without bromine atoms yielded the same chromosomal staining pattern as the other antibody

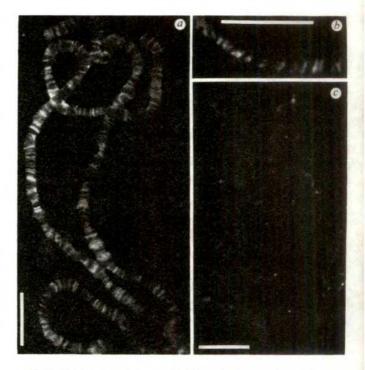

Fig. 2 Fluorescence micrographs of polytene chromosomes demonstrating the specificity of the reaction between anti-Z-DNA antibody and fixed chromosomes. a, Chromosomes stained with anti-Z-DNA antibody by our standard procedure. b, Chromosomes stained with anti-Z-DNA antibody, which had been preincubated with poly(dG-dC)-poly(dG-dC) in the B conformation. The pattern of fluorescence staining is identical to that produced by the antibody without B-DNA competitor. c, Chromosomes stained with anti-Z-DNA antibody, which had been preincubated with the Z-form brominated poly(dG-dC) poly(dG-dC). No chromosomal fluorescence staining is detectable although the precipitated antigen-antibody complex produces an increased general background of fluorescence. Salivary glands were dissected out of third instar Oregon R larvae (gt-1 stock) into a droplet of 45% acetic acid in Ringer's buffer on a coverslip. After 2-5 min a microscope slide was touched to the drop on the coverslip, the gland was squashed mechanically and the slides were placed on the flat surface of a block of dry ice. After 20 min freezing on dry ice the coverslips were pried off and the slides were briefly immersed horizontally in PBS. Excess PBS was removed from the slide without completely drying the surface; 0.02 ml antibody-containing PBS solution was then added and incubated for 15 min at 37 °C. The slides were then gently washed in PBS and fluorescein isothiocyanate (FITC) conjugated IgG fraction of goat anti-rabbit serum (Cappell) was added at a 1:250 dilution in PBS, followed by another 37 °C incubation for 15 min. Unbound FITC-conjugated secondary antibody gently washed out and a clean coverslip was mounted with a drop of PBS. The slides were viewed and photographed in a Zeiss microscope using both incident UV illumination and phase contrast optics. Photographs were taken using Kodak Ektachrome 400 film. For the blocking experiments of b and c, the antibody solutions contained the respective competitor DNAs at concentrations of 0.5 mg ml-1 and were preincubated for 30-45 min at 37 °C before staining of the polytene chromosomes. Scale bar, 10 µm.

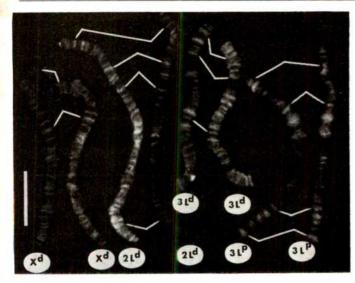

Fig. 3 Fluorescence micrographs of chromosomes stained with the anti-Z-DNA antibody demonstrating the constancy of the fluorescence pattern from nucleus to nucleus. Sections of chromosomes from different nuclei are aligned and selected fluorescent regions are marked to orient the viewer. d marks the most distal sections of chromosome arms X, 2L and 3L; p designates the proximal part. Fluorescence staining and visualization was done as described in Fig. 2. Scale bar, 10 μm.

preparations. None of the normal rabbit sera which we have used nor incubation with fluorescent labelled goat anti-rabbit antibody alone has produced staining of the polytene chromosomes. Thus, all our control experiments indicate that the anti-body is recognizing the Z-conformation in the polytene chromosomes, as it does in the immunoprecipitation experiments.

The anti-Z-DNA antibodies produce a distinctive pattern of staining on the polytene chromosomes; the fluorescent segments seen on the chromosome vary both in size and intensity, but the size and staining intensity of any particular region is reproducible and appears to reflect the nature of the chromatin. Figure 3 shows several examples of chromosomal segments from different nuclei. The reproducibility of the staining pattern is most conveniently seen when the two homologues that make up a chromosome have become unpaired along a part of their length. Figure 4 shows two examples that demonstrate the similarity of the staining pattern in the asynapsed chromosomes.

Some of the fluorescence photographs in Figs 2–4 were exposed for long periods to give a stronger fluorescent signal. However, photographs were also taken with a shorter exposure so that the image would be in the linear range of the film response, and here, the darker non-fluorescent segments were as dark as the general background. From analyses of negatives of these photographs using a densitometer tracing to look at the variations in the amplitude, we estimate that the intensity of different fluorescent segments roughly varies by a factor of 5–10 in brightness.

To determine which segments of the *Drosophila* chromosome are fluorescing, we compared the pattern of bands seen in phase microscopic photographs with the fluorescence pattern (Fig. 5). Photographs of segments from various parts of the *Drosophila* chromosome were cut along the chromosomal axis and the phase photographs were compared with the fluorescence photographs. Figure 5 shows that the fluorescent segments are the interbands and not the bands. The bright areas in the fluorescence photograph are found in the position of the light interband regions in the phase photographs. Note that there is not necessarily a correlation between the width of the interband segment and its fluorescent intensity.

Thus, the antibody binding results shown in Fig. 1, together with the negative controls, clearly demonstrate that we are using an antibody that is specific for the Z-DNA helix. It reacted with three polymers only in distinct conditions required for each to occur in the Z conformation, and did not react with E. coli DNA in any of these conditions, nor with single-stranded DNA and a

variety of polynucleotides, including brominated polymers. The bromination was not required either for induction of Z-specific antibody or for its serological reactivity. The antibody that binds to polytene chromosomes shows the same properties as those measured in the binding experiments; chromosomal staining is blocked only by molecules that have a Z conformation and yield an immune precipitate with the antibody.

## Tests for effects of experimental procedures

As the chromosomes in almost all cytological preparations have been subjected to treatments that remove or alter cellular components, this raises the question of whether sample preparation induces formation of Z-DNA in the polytene chromosomes. At present, the only way we can approach this question is by testing the effects of various preparative procedures, and we have therefore tested preparations from salivary glands that were incubated for 2-5 min at room temperature in 45% acetic acid, squashed in the same solution, frozen on dry ice and treated in various ways before incubation with antibody. After freezing and removal of the cover slips, the slides were: (1) placed directly in phosphate-buffered saline (PBS), or (2) immersed in ethanol, air dried and then placed in PBS, or (3) placed directly in a post-fixative solution containing 3.7% formaldehyde and then in PBS. Alternatively, glands were fixed by the formaldehyde technique of Silver and Elgin<sup>12</sup> squashed in 45% acetic acid with 10 mM MgCl2 and frozen on dry ice, then immersed in ethanol and air dried before incubation with antibody in PBS.

These treatments might be expected to produce different types of artefact, yet all result in qualitatively the same staining pattern. The first procedure produces by far the most intense staining pattern and has been used as our standard preparative technique. Less intense staining occurred when formaldehyde was used for fixation and so further study will be required to determine whether bright staining was due to selective removal of proteins during exposure to 45% acetic acid. In the post-fixed preparations it is likely that the formaldehyde is itself blocking the antibody binding site.

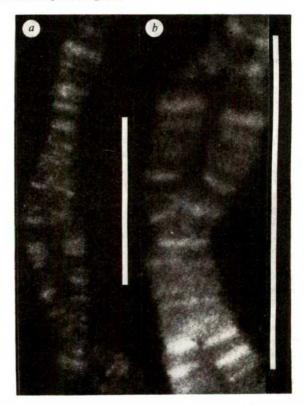

Fig. 4 Reproducibility of the anti-Z-DNA antibody staining pattern as seen in two examples of asynapsis (a, b). The unpaired homologues of a polytene chromosomal arm show very similar fluorescence staining in the homologous regions. Experimental protocol was as described in Fig. 2.

The polytene chromosome is segmented into bands and interbands. The bands vary in size, yielding a banding pattern that is invariant unless chromosomal rearrangements occur. These banding patterns are useful for genetic mapping studies and for studies of evolutionary relationships between species; however, their role in chromosome structure is unknown. Banded polytene chromosomes have also been reported in several other eukaryotic organisms including protozoa and plants13. It has been suggested that this banding might be a general property of the organization of the eukaryotic chromosome<sup>13</sup>. Drosophila has ~5,000 bands as well as interbands which have been identified and mapped. On average, a band plus interband contains some 30 kilobases of DNA<sup>13</sup>. The DNA in the interband has been estimated as ranging from 5% (ref. 13) to 30% (ref. 14) of the total DNA, depending on the method of measurement. Electron micrographs of Drosophila chromosomes show bands as containing darkly staining, densely clumped units while the interbands are visualized as elongated fibrils 50-60 Å in diameter13. Indirect immunofluorescence has revealed a number of proteins in the bands 15-17 and interbands 16-18

An important question in any immunofluorescence experiment is whether the antigen is present but not accessible for reaction. This question is especially relevant to our experiments because staining is limited to the least compact regions of the chromosomes. Although anti-histone antibodies can cause brighter staining in the more compact regions than in interbands is it is possible that the DNA, or a particular portion of it, is not as available as the histones. Although we cannot rule out the presence of Z-DNA in the band regions, our experiments do show that it is either more abundant or more accessible in the interbands. Either of the alternatives is interesting and a decision between the alternatives may help explain the significance of chromosomal banding. This question is under further study with antibodies that react with other forms of DNA.

The reproducibility and uniformity of the staining pattern throughout the entire length of the polytene chromosome are remarkable. We have compared the staining pattern among different giant polytene chromosomes within an individual and between individuals. The staining pattern of Z-DNA antibodies appears to be a constant feature of the chromosomes in much the same way that the banding in the phase contrast microscope appears constant. This suggests that the pattern is an intrinsic property of the chromosome rather than, for example, a property induced through the mechanical action of squashing the chromosome, for then one would expect significant differences in the staining pattern in various parts of the chromosome, depending on the degree of mechanical stress to which each segment was subjected.

The intensity of staining in different interbands varies considerably, and seems to be unrelated to the width of the interband; the origin of the variability is not known. The possibility that the brighter segments contain a larger number of closely packed and unresolved band-interband units is unlikely, because we have occasionally seen extremely stretched regions in which the interbands are considerably extended and still do not break up into smaller fluorescent segments.

It would be interesting to know the proportion of the interband DNA that needs to be Z-DNA to produce the observed fluorescent pattern. This is difficult to estimate because we have no absolute standard which will allow us to determine accurately the amount of primary antibody bound from the amount of fluorescence detected. As a lower limit it is possible that only a small stretch of some 6–8 base pairs out of the 3 kilobase pairs in the average interband might be in the Z conformation. In a polytene chromosome, where 1–2,000 copies of such a sequence are lying in register, one would have enormous numbers of antibodies arrayed transversely across the interband. Because of the limited optical resolution in the light microscope and the broadening of the fluorescent image, one site would appear to occupy the entire 0.1 μm of an average interband. As an upper

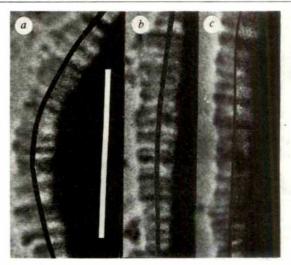

Fig. 5 Comparison of phase contrast and anti-Z-DNA antibody-stained fluorescent photographs of polytene chromosomes. Chromosome sections from three different nuclei (a-c) are shown. Analogous sections of the same chromosome are compared by cutting the photographs down the chromosomal axis and comparing the two halves. The light areas of the left phase contrast photographs correspond to the interbands while the darker sections are the bands. The white sections of the right darkfield fluorescent photographs show the position of the anti-Z-DNA fluorescent stained antibodies. It can be seen that the interbands are fluorescing. Note that the intensity of fluorescence is not necessarily related to the width of the interband. Fluorescence staining was done as described in Fig. 2 legend. Scale bar, 5 μm.

limit, the entire interband could be in the Z-DNA conformation. Although this seems implausible, further work will be required before we can make a more accurate estimate.

## Possible functional significance of Z-DNA

Because the Z conformation is a reversible structural form of DNA it is an attractive candidate for having a regulatory role in genetic activity. Many regions of the polytene chromosomes undergo changes in chromatin structure, called puffs, which are associated with transcription of certain genes. The patterns of Z-DNA staining during such structural changes will be of obvious interest.

In physiological salt conditions the Z-DNA conformation is somewhat less stable than the B conformation and therefore has to be stabilized. There may be four ways of maintaining the Z conformation in biological systems. (1) Supercoiling. Z-DNA twists the double helix in a left-handed mode, opposite to the right-handed B-DNA conformation. Because of this one can interchange strongly negative supercoiled DNA for segments of Z-DNA (L. Peck, A. N., A. R. and J. C. Wang, in preparation). (2) Binding to proteins which are specific for the Z conformation. These probably involve electrostatic interactions with basic residues. (3) Binding to specific ions. For example, spermine or spermidine can stabilize crystals of Z-DNA so that they form with a regularity which yields an atomic resolution diffraction pattern<sup>1,7</sup>. (4) Modification such as methylation of . (4) Modification such as methylation of cytosine in the 5 position (although not necessarily applicable to Drosophila DNA19). In the absence of methylation poly(dGdC) poly(dG-dC) requires 700 mM Mg2+ to convert to the Z conformation. Behe and Felsenfeld11 have shown that when the methyl group is present, the Z conformation is formed in 0.6 mM Mg<sup>2+</sup>. It is interesting that spermine is even more effective, forming the Z conformation at a concentration of 0.002 mM. Further work must be done before we fully understand the parameters which stabilize the Z conformation in the polytene chromosome.

Work with synthetic deoxypolynucleotides has amply demonstrated that there is a reversible equilibrium between the right-handed B conformation and the left-handed Z conformation in molecules in which there is an appropriate sequence. Recent work with cloned segments of poly(dG-dC) poly(dG-dC) in plasmids have demonstrated that it is possible for these segments to undergo a B to Z transformation even though they

are enclosed in plasmid segments containing B-DNA (ref. 20 and L. Peck, A. N., A. R. and J. C. Wang, in preparation). It is thus reasonable to imagine that appropriate segments in chromatin might undergo similar changes in conformation. Z-DNA segments may have the property of not only changing the local environment near a particular gene, but through interaction with supercoiling these segments could modify the transcribability of DNA regions far removed from the site at which the Z-DNA segment is found.

The striking observation here is that an antibody specific to left-handed Z-DNA binds in a regular fashion to the interband regions of the D. melanogaster polytene chromosomes. Our control experiments strengthen the conclusion that this binding

is due to a Z-DNA conformation found in the interbands. Band-interband units seem to be basic units of gene activity<sup>13</sup> replication<sup>21</sup> and perhaps chromosomal synapsis. It is tempting to suppose that Z-DNA might be a conformational switch which is involved in the control of transcription or of other of these activities. As Z-DNA appears to be a fundamental component of the polytene chromosome, these chromosomes may provide a unique opportunity for further exploration of the role of Z-DNA.

## **Dual function transcripts specifying** tRNA and mRNA

## Lynn Hudson, John Rossi\* & Arthur Landy

Section of Microbiology and Molecular Biology, Division of Biology and Medicine, Brown University, Providence, Rhode Island 02912, USA

A cluster of four tRNA genes in Escherichia coli is co-transcribed with an adjacent gene encoding elongation factor Tu. The resultant transcript that specifies both structural (tRNA) and informational (mRNA) RNA may not be an uncommon occurrence and has interesting regulatory implications.

IN Escherichia coli, where regulation of transcription has been most extensively studied, the RNAs synthesized are generally divided into two categories—the class of informational or mRNAs that are metabolically unstable, and the class of structural RNAs such as rRNA and tRNA that do not show appreciable turnover. The two classes are also distinguishable by their regulation pathways. In particular, stable RNA is subject to a coordinate regulation that is responsive to the availability of amino acids for protein synthesis. In general, this type of control only affects informational RNAs encoding proteins required in protein synthesis.

Transfer RNA genes are distributed throughout the E. coli genome as part of ribosomal RNA operons or as clusters of tRNA genes containing either different tRNA genes or repeats of the same gene (for review see ref. 1). We report here a novel transcription unit composed of a tRNA cluster and mRNA and suggest that the co-transcription of structural and informational RNA may not be an uncommon occurrence. Possible implications of these dual function transcripts are also discussed.

## Organization and structure of the tyrU gene cluster

The tyrU gene cluster is situated between the rmB ribosomal operon and the tufB gene at 89 min (ref. 2). The tyrU locus encodes the major tyrosine accepting species, tRNA2Tyr, which

\* Present address: Department of Molecular Genetics, Division of Biology, City of Hope, Duarte, California 91010, USA.

occurs as a single copy within a cluster of three other tRNA genes<sup>3-5</sup>. The tufB locus codes for elongation factor (EF)-Tu, which promotes the binding of aminoacyl-tRNA to ribosomes. In addition to its key role in translation, EF-Tu functions as a structural component of  $Q\beta$  replicase (see ref. 6 for review). Figure 1 shows the DNA sequence of the tyrU gene cluster

and the 5' end of the adjacent tufB gene, which is located only 114 base pairs (bp) downstream of the tRNA cluster. The tyrUpromoter (as identified by hybridization analyses presented below) is located directly upstream of the first tRNA gene in the cluster and shares two features with the tyrT promoter region: a region of G-C bias flanking the Pribnow box (Fig. 1 and ref. 7), and wo dyad symmetries, one involving the -35 region and the other centred near the Pribnow sequence (Fig. 1 and ref. 8). These sequence features are present in the promoter regions of other stringently controlled genes and may therefore have a role in their coordinate synthesis. The Pribnow box participates in a dyad symmetry in the ribosomal protein operons and the G+C-rich sequence following the Pribnow heptamer has been noted for rRNA and ribosomal protein operons<sup>10</sup>.

## A co-transcript of tRNA and mRNA

Knowledge of the organization and structure of the tyrU cluster and adjacent tufB gene has facilitated analyses of the in vivo transcripts and processing intermediates. The methods developed by Alwine and co-workers<sup>11</sup> were used to detect RNA species that comprise a small fraction of the total cellular RNA. The experimental approach involved fractionating denatured RNA by gel electrophoresis, transferring the RNA to diazobenzyloxymethyl (DBM) paper and probing the RNA blots with radiolabelled restriction fragments isolated from the tyrU region (as detailed in Fig. 2 legend). Detection of RNA precursors was maximized by using E, coli strains deficient in RNA processing. Precursor tRNAs accumulate in these strains as a result of mutations blocking and/or delaying their processing<sup>12</sup>.

Figure 2 shows results of this analysis for selected probes. The tRNA-specific probe (Fig. 2 B) hybridized to one band of 1,800 bases (transcripts smaller than  $\sim$ 700 bases were detected on the higher composition gels shown in Fig. 5). The tufB probe (Fig. 2 C) also hybridized to the 1,800-base transcript, as well as to four other transcripts sized at 4,700, 1,550, 1,420 and 1,290 bases. As detailed below, the 4,700-base transcript contained sequences from the other gene encoding EF-Tu, tufA (ref. 13), and the lower molecular weight transcripts probably represent tufA and tufB processing intermediates. The probes immediately upstream (Fig. 2 A) or downstream (Fig. 2 D) of the tRNA-tufB region did not hybridize to the 1,800-base transcript. This collection of probes thus defines a transcript of 1,800 bases which contains sequences from both the tRNA gene cluster and the tufB gene.

The 1,800-base transcript was further characterized by

sequential hybridizations using probes covering different portions of the tyrU region. Figure 3 summarizes the hybridization results. Eight probes isolated from regions of structural tRNA or tu/B sequence displayed hybridization to the 1,800-base transcript. Importantly, the sum of the restriction fragments that hybridized to the co-transcript corresponds to the molecular weight of the transcript (1,800 bases) determined on denaturing gels. Probes that failed to hybridize to the 1,800-base transcript defined the outer limits of the transcript: the 5'-proximal probe that produced negative results was separated from the structural tRNA<sub>4</sub><sup>Thr</sup> sequence by 12 bp and the 3'-proximal probe began 85 bp downstream of tu/B structural sequence. Thus, this series of probes specified a transcript encompassing both the tRNA cluster and the tu/B gene.

To establish these unexpected results unequivocally, control experiments were carried out to ensure that: (1) failure to detect hybridization with the negative probes was not due to insufficient radioactivity, and (2) the observed hybridization with the positive probes was not the result of either contamination (with other labelled DNA) or the result of fortuitous homologies. The ability of each nick-translated probe to produce a strong hybridization signal to its respective band and to no other fragments of a digest of  $\lambda$  riff 18 DNA was tested. As

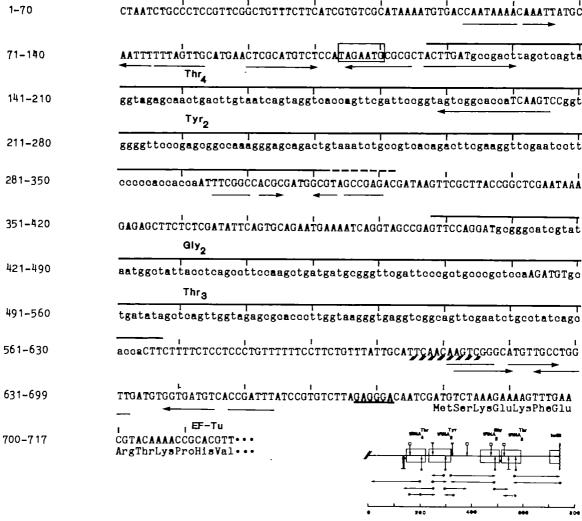

Fig. 1 Nucleotide sequences of the tyrU cluster and proximal ta/B region. The DNA strand with the sequence of the RNA transcript is shown. The source of DNA was the transducing phage λ rm<sup>4</sup>18 (ref. 51; supplied by M. Nomura or N. Fill). DNA sequencing was by the method of Maxam and Gilbert<sup>52</sup>; \*, 5'-labelled end of the restriction fragments; →, direction and extent of the sequence obtained, the scale is in base pairs. Complement and overlap were obtained for all new sequences reported here with the exception of the sequence upstream of the tRNA<sub>4</sub><sup>The</sup> gene. The sequence is identical to that reported by An andProsen<sup>16</sup> with the exception of an additional base pair they place at position 317. Structural tRNA sequence (lower case) and the two dimeric procursors are overlined. The tRNA<sub>2</sub><sup>Che</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub><sup>The</sup>-(RNA<sub>4</sub>-(RNA<sub>4</sub>-(RNA<sub>4</sub>-(RNA<sub>4</sub>-(RNA<sub>4</sub>-(RNA<sub>4</sub>-(RNA<sub>4</sub>-(RNA<sub>4</sub>-(RNA<sub>4</sub>-(RNA<sub>4</sub>-(RNA<sub>4</sub>-(RNA<sub>4</sub>-

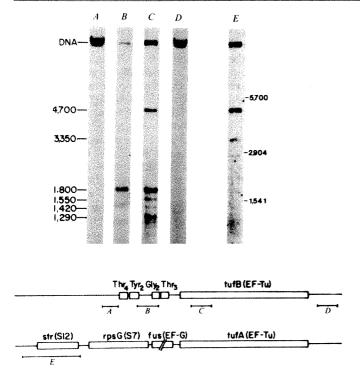

Fig. 2 Characterization of the transcript specifying the tyrU cluster and tufB. E. coli strain ABL-1 (RNase III RNase Pt; ref. 55; gift of W. McClain) was grown for several generations at 30 °C, and then incubated at 42 °C for 30 min to inactivate RNase P. RNA was extracted according to Gegenheimer and Apirion<sup>55</sup> as detailed elsewhere<sup>30</sup>, denatured with glyoxal<sup>56</sup>, electrophoresed in 1.5% agarose gels with recirculation of the 10 mM sodium phosphate, pH 6.5, 1 mM EDTA running buffer, and transferred to DBM paper<sup>11</sup>. The RNA blots were probed with DNA fragments (A-E) which were nick translated<sup>57</sup> with [ $\alpha$ - $^{32}$ P]dCTP (NEN; 2-3,000 Ci mmol<sup>-1</sup>) to a specific activity of  $\sim 5 \times 10^7$  c.p.m. per µg. Hybridizations were carried out in the presence of 10% dextran sulphate as detailed by Alwine *et al.*<sup>11</sup> but omitting carrier DNA. Blots were washed first in 0.3 M NaCl, 0.03 M sodium citrate, 0.1% SDS at 23 °C for 20 min, and then in 15 mM NaCl, 1.5 mM sodium citrate, 0.1% SDS for 45 min at 50-55 °C. The 32P-labelled probes isolated from the region of  $\lambda$  rif<sup>d</sup> 18 depicted in the diagram were: A Hhal-145; B, Hintl-190; C, Hincll-Smal-187; D, BstNl-HaeIII-185. Probe E is a HaeIII-530 fragment encompassing the S12 ribosomal protein gene, which was isolated from \( \lambda \) fus3 (obtained from J. Yates and M. Nomura). Molecular weight markers were 16S (1,541 bases), 23S (2,904 bases) and 30S RNA ( $\sim$ 5,700 bases). Lanes B, C and E have  $\sim$ 2 µg RNA per lane, and lanes A and D have 30  $\mu$ g per lane. The scale is in bases. Structural sequences for tRNAs and tufB are boxed.

shown in Fig. 4 for selected probes and detailed in the legend, each probe hybridized only to its corresponding  $\lambda$  rif<sup>d</sup>18 restriction fragment.

The hybridization results place the promoter for the tRNAtufB co-transcript directly before the tRNA4 gene and the terminator closely following the tufB structural sequence. Note that these assignments are not precise, because a probe could share as much as 30 bases of homology with the transcript and fail to hybridize. Genetic evidence corroborates the location of the tufB promoter directly upstream of the tRNA cluster<sup>60</sup>. In addition, Taylor and Burgess<sup>14</sup> found that a restriction fragment containing the presumptive tRNA-tufB promoter (labelled HaeIII-890 by Taylor and Burgess<sup>14</sup> and HaeIII-700 by Rossi et al. 15) formed filter-retainable complexes with RNA polymerase. Finally, inspection of the DNA sequence reveals a promoter region situated directly before the tRNA<sub>4</sub><sup>Thr</sup> gene (see Fig. 1), a location consistent with the analyses of the functional promoter. The location of a possible termination sequence 34 bases following tufB (ref. 16) is also consistent with our hybridization results (Fig. 3). That termination occurs at this site in vivo is also suggested by the presence of gene U, which is transcribed from its own promoter ~200 bases downstream of tufB (refs 16, 17).

## Other EF-Tu transcripts

EF-Tu is encoded by duplicate genes that contribute approximately equivalent amounts of EF-Tu to the cell<sup>18,19</sup>. The two proteins differ only in the carboxy-terminal amino acid<sup>19</sup>, suggesting that they are functionally equivalent. The other gene for EF-Tu, tufA, is located at 72 min as the terminal gene of the str ribosomal protein operon<sup>13</sup>. The str-rpsG-fus-tufA genes are transcribed from a single promoter<sup>13</sup> located 80 bp upstream of str structural sequence<sup>20</sup>, which could yield a primary transcript with an estimated size of 4,800 bases.

Probes prepared from tufB structural sequences hybridize to both tufA and tufB transcripts, as the DNA sequences of tufA and tufB differ at only 13 of 1,181 bp<sup>16,21</sup>. The largest tuf transcript was suspected to be tufA specific, as probes immediately upstream and downstream of the tRNA-tufB region failed to hybridize to it (Fig. 2). A probe isolated from the 5' end of the str operon was used to prove that the 4,700-base transcript encoded the str operon. The str probe hybridized to the 4,700base transcript that was also detected with the tufB structural probe (Fig. 2 E), indicating that the 4,700-base transcript corresponds to a full-sized str operon mRNA. This same probe also hybridized to a 3,350-base message that did not hybridize with tufB structural probes and could therefore encode the first three genes of the str operon (str-rpsG-fus). Our present data do not indicate whether the three smallest RNAs (1,290, 1,420, 1,550 bp (originate from tubB or tufA or both. As determined by densitometric tracings, these small RNAs are less abundant than the major 1,800-base transcript (by 2-, 22-, and 6-fold for 1,290-, 1,420- and 1,550-base transcripts respectively).

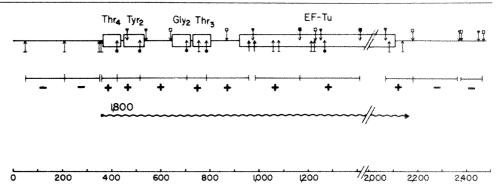

## Modes of EF-Tu synthesis

The presence of one copy of EF-Tu in a ribosomal protein operon and the other in a tRNA operon may be important in coordinating the synthesis of these three components of the translational machinery. The intracellular concentration of EF-Tu does, in fact, parallel that of tRNAs and ribosomes during changing growth conditions in *E. coli*<sup>22-24</sup>. Moreover, EF-Tu synthesis from both loci is subject to stringent control in response to amino acid starvation<sup>23,25-28</sup>.

In addition to transcripts corresponding to full-size str operon (4,700 bases) and tRNA-tufB operon (1,800 bases), there are three smaller tuf messages (1,290, 1,420 and 1,550 bases) (see Fig. 2). The 1,290-base message corresponds to the non-tRNA cleavage product of the 1,800-base primary transcript as shown in Fig. 5. In addition, an RNA of this size could result from transcription initiating at a promoter site (TGATGTC) located 32 bases upstream of tufB. Indeed, some promoter activity has been observed in this region in vivo 60. The intergenic region also contains a possible termination sequence (CAACAA; refs 29, 30) that overlaps a sequence (TTCAACAAGTC) postulated to be involved in processing because of its homology with the characterized tyrT processing site (ref. 31; see also Fig. 6). Due to this overlap the alternative, non-mutually exclusive pathways that could uncouple EF-Tu synthesis from that of the tRNA cluster (processing versus termination and re-initiation of transcription) cannot be distinguished. However, the presence of large amounts of the 1,800-base transcript (Fig. 2) indicates that termination following the tRNA cluster (if it occurs at all) cannot be very effective in these growth conditions.

A similar potential for uncoupling exists at the *tufA* locus. The 3,350-base *str-rpsG-fus* message (Fig. 2) could result from either a termination or processing event or both. Analogous to the *tufB* region, promoter activity of DNA segments directly upstream of *tufA* has been observed *in vivo* (ref. 21 and J. D. Friesen and co-workers, personal communication). As noted below, the processing site conserved between the *tyrT* and *tyrU* transcripts is also present in the *fus-tufA* intergenic region, a finding that favours processing as a mode of uncoupling. Consistent with the suggested uncoupling of *tufA* synthesis, Nomura and co-workers find that translational repression of *str* 

Fig. 3 Organization and transcription of the tRNA-tufB region. The locations of the restriction sites were obtained from the sequence shown in Fig. 1 or ref. 16. Hybridization to the 1,800-base transcript (~) is denoted by a + in the appropriate restriction fragment (from Arif<sup>d</sup>18) and lack of hybridization by -The HinfI-82 probe from the tRNA region hybridized strongly to 16S RNA in addition to the 1,800-base transcript. This result is consistent with the presof a number of 12-16-bp homologies between 16S RNA<sup>58</sup> and tRNA<sup>Thr</sup> sequences. Due to the hybridization with 16S RNA, the Hinfl-82 probe could not be used to determine

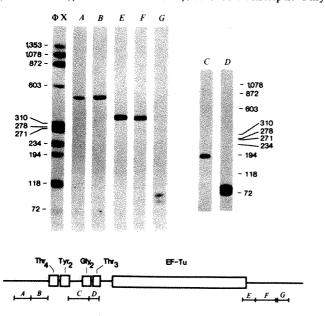

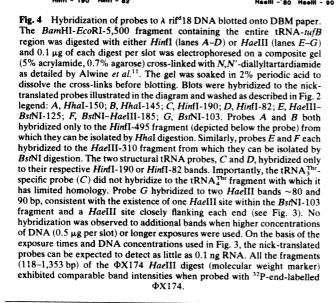

whether the smaller *tuf* transcripts (1,550 and 1,420 bases shown in Fig. 2) were *tufA* or *tufB* specific. The scale is in bases. Structural sequences for the tRNAs and *tufB* are boxed. \$\forall\$, Bst1; \$\div\$, HaeIII; \$\div\$, HincII; \$\div\$, HincII; \$\div\$, Smal.

operon by S7 protein does not inhibit EF-Tu synthesis in vitro 32,33 or in vivo (M. Nomura, personal communication).

## Processing intermediates of the tyrU cluster

Figure 5 gives the tRNA processing intermediates of the 1,800-base primary transcript. Each probe hybridized to mature tRNA (75-85 bases), the 495- and the 1,800-base transcripts. Only

Hinfl - 485

tRNA<sub>4</sub><sup>Thr</sup> or tRNA<sub>2</sub><sup>Tyr</sup> probes hybridized to a 200-base transcript; similarly, only tRNA<sub>2</sub><sup>Gly</sup> or tRNA<sub>3</sub><sup>Thr</sup> probes hybridized to a 170-base transcript. The data suggest a processing scheme (depicted in the lower portion of Fig. 5) in which the primary transcript is initially processed to a 495-base transcript containing the tRNA cluster and a *tufB* mRNA of ~1,300 bases (Fig. 2). The tRNA precursor is subsequently processed to two dimeric precursors, a 200-base transcript containing tRNA<sub>4</sub><sup>Thr</sup> tRNA<sub>2</sub><sup>Tyr</sup> and a 170-base transcript containing tRNA<sub>2</sub><sup>Gly</sup> tRNA<sub>3</sub><sup>Thr</sup>. Both these dimers are very close in size to those previously isolated from an *E. coli* strain with thermolabile RNase P activity<sup>34-36</sup>.

A secondary pathway for processing the tRNA-tufB transcripts may exist in RNase P-deficient strains. A 415-base transcript was apparent in lanes probed with A, B and C but not D, suggesting that this transcript consists of a tRNA\_T^{Dr}-tRNA\_2^{Gly} trimer. This trimer may result from cleavage of either the 1,800- or 495-base transcript between the tRNA\_2^{Gly} and tRNA\_T^{Dr} structural genes.

The positions of the  $tRNA_2^{Thr}$ - $tRNA_2^{Tyr}$  and  $tRNA_2^{Gly}$ - $tRNA_3^{Thr}$  dimers, based on the size of the processing intermediates (Fig. 5) or obtained from the sequence of the  $tRNA_2^{Gly}$ - $tRNA_2^{Thr}$  dimer<sup>34</sup>, are shown in Fig. 1. The long spacer separating the two dimers is similar to that found in tyrT (ref. 37) and supB-supE (ref. 38) and may be a common feature of tRNA clusters. The 114-base spacer separating the tRNA cluster and tufB is characterized by a 34-base C+T-rich region directly following the tRNAs.

The endonucleases responsible for cleaving the 1,800-base primary transcript have not been identified. One candidate was RNase III; however, there was no significant difference in the transcripts isolated from strains with or without functional RNase III (ABL-1 compared with A49). Other candidates include the tRNA processing endonuclease(s) partially purified by several laboratories<sup>36,39-41</sup>. It is of interest that the sequence conserved between the *tyrT* and *tyrU* primary transcripts, which is apparently the site for cleaving the tRNA cluster<sup>31</sup> from the distal message (see Fig. 5), is also present in the *fus-tufA* intergenic region<sup>21</sup> (TACCAAAGTC matches in 8 of 10 positions). The existence of a conserved processing site suggests that a single endonuclease may coordinately control EF-Tu processing from the *tufA* and *tufB* transcripts.

Finally, we note that in cells wild type for processing enzymes (CA274), the 1,800-base transcript is the only tyrU precursor detectable; none of the tRNA processing intermediates can be seen. Furthermore, as the amount of 1,800-base transcript in CA274 is comparable with that observed in cells deficient for processing (RNase Pts or the double mutant RNase III RNase Pts), we suggest the tRNA sequences on the 1,800-base transcript are matured and function as tRNA in the cell.

## Generality of dual function transcripts

The presence of tRNA on the same transcript as mRNA may not be rare in prokaryotes. An analysis of the  $in\ viv\theta$  transcripts of the  $tRNA_1^{Tyr}$  gene in  $E.\ coli$  has revealed a 650-base transcript

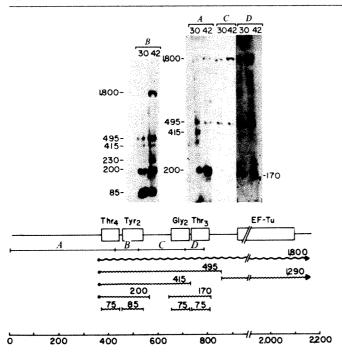

Fig. 5 Processing intermediates of the tyrU cluster. RNA was extracted from E. coli strain A49 (RNase Pts; ref. 59; gift of W. McClain) grown at either 30 or 42 °C, electrophoresed on 2% agarose gels at 30 µg RNA per slot and blotted onto DBM paper. Transfer conditions were similar to those described for Fig. 2 except that glyoxal was removed with a lower concentration of sodium hydroxide (10 mM compared with 50 mM for Fig. 2). Molecular weight markers were 5'-end-labelled *Hae*III and *Hin*cII fragments of  $\Phi$ X174. The gel shown in *B* was electrophoresed for a shorter time to retain mature tRNA. The <sup>32</sup>P-labelled probes isolated from the regions of A rif<sup>d</sup>18 illustrated in the diagram were: A, Hinf1-420; B, Hinf1-93; C, HinfI-190; D, HinfI-82. The putative primary transcript (\*\*), processing intermediates and mature tRNAs (m) are labelled by their respective sizes (in bases) on denaturing gels. The probe containing the structural tyrosine tRNA sequence (B) hybridized to a 230-base transcript that also hybridized with a tRNA<sub>1</sub><sup>Tyr</sup> upstream probe and must therefore be a tyrT transcript. Probe C contained only 18 bases of structural tyrosine tRNA sequence, which severely limited its binding to the 200- or 230-base tyrosine transcripts in the stringent washing conditions used in these experiments. In the blot shown, the hybridization of probe C to the 170-base transcript did not photograph; in other blots this probe detectably bound the 170-base transcript. The processing scheme is discussed in the text

which, in addition to containing two tRNA<sub>1</sub><sup>Tyr</sup> sequences, can code for a small arginine-rich protein<sup>30</sup>. The putative basic protein is encoded by the first of the three repeated units that follow the tRNA<sub>1</sub><sup>Tyr</sup> structural gene<sup>37</sup>. That the *tyrT* transcript actually encodes protein is suggested by the *in vitro* production of a low molecular weight, basic protein that maps to the first repeat<sup>61</sup>.

Transcripts of the tyrT and tyrU gene clusters share several interesting features (Fig. 6): (1) the 5' portion of both transcripts

consists of two regions of cloverleaf secondary structure that are separated by a long spacer (115-208 bases), (2) the tyrosine structural sequences present on each transcript are almost identical, differing by only two bases in the variable loop region <sup>42</sup>, and (3) following the tRNA region there is an intergenic spacer of 67-114 bases containing a conserved sequence (TTCAAAAGTC; located in a region of dyad symmetry) which seems to be the site for processing the tRNA cluster from the mRNA portion of the transcript (ref. 31 and Fig. 5). Finally, the proteins encoded by the two transcripts may share the property of being produced in large quantities by the cell. EF-Tu represents as much as 5% of the total cell protein in E. coli<sup>22,24,43,44</sup>. The basic protein encoded in the tyrT transcript, if actually a DNA-binding protein as suggested by its resemblance to the basic protamines<sup>61</sup>, might also be expected to be relatively abundant.

Co-transcription of tRNA and mRNA has also been observed in other systems. In mitochondria, where transcription initiates at a unique site, almost every protein coding sequence is directly flanked by a tRNA gene<sup>45-47</sup>. Although the co-transcript seems to be very unstable, this arrangement may provide a requisite economy of space in the genome and/or conveniently placed processing signals in the nascent RNA<sup>45,47</sup>. Another system is bacteriophage T4, where a cluster of eight tRNAs is transcribed from the *ipI* promoter located 1,000 bases upstream<sup>40,48</sup>.

## Physiological implications

The tRNA secondary and/or tertiary structure could stabilize adjacent mRNA by retarding the usually rapid 5' to 3' degradation of message<sup>49</sup>. Detection of substantial quantities of intact dual function transcript in cells wild type for processing enzymes is consistent with a stabilization role for the tRNA cluster. If mRNA stabilization is important, the results of Pedersen et al. imply that the tRNAs must be removed before translation. They observed that decay of protein synthetic capacity for tufA and tufB differed by less than 20 (ref. 50). In these experiments, RNA synthesis was inhibited by rifampicin or streptolygidin and it is possible that cleavage between the tRNA and tufB mRNA was also impaired. This would mask any storage form of the transcript that could be activated for translation by cleavage of the proximal tRNA. Alternatively (not mutually exclusive), co-transcription of tRNA and mRNA may be viewed as a mechanism for coordinately controlling the synthesis of key proteins with those of stable RNAs, thereby regulating the production of a particular protein with the growth requirements of the cell.

#### **Conclusions**

Analyses of the structure and transcription of the tyrU locus have revealed a new class of tRNA gene. Transfer RNA genes can be categorized by their proximity and co-transcription with

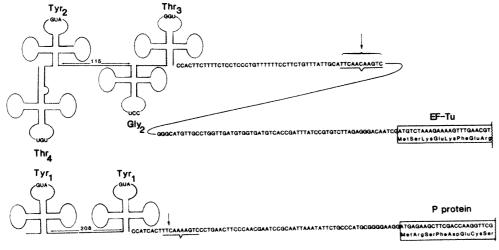

Fig. 6 Comparison of the tyrT and tyrUprimary transcripts. The tyrT transcript was characterized by Rossi et al. RNA extracted from an RNase Pis E. coli strain infected with  $\Phi 80 \text{ psu}_3^{+,-}$  (doublet). The site conserved between the tyrT and tyrU gene clusters and known to be a 3'-processing site for tyrT transcripts31 is underlined. For tufB (ref. 19) and for the protamine-like protein (P protein; see text), the first eight amino acids are indicated. Translation of P protein also initiates at the methionine located 4 codons upstream of the start site shown, as indicated by the in vitro production of both a 29- and 33-amino acid basic protein that map to the first repeat<sup>6</sup>

either rRNA genes, other tRNA genes and/or genes encoding protein. It is tempting to speculate that the tRNA secondary and/or tertiary structure provides an additional level of posttranscriptional control for dual function transcripts. The precise role of the tRNA molecules on the co-transcript remains to be defined.

## **Recurrent Seyfert** activity in spiral galaxy nuclei

## R. H. Sanders

Kapteyn Astronomical Institute der Rijksuniversiteit te Groningen, Nettelbosje 2, 9700 AV Groningen, The Netherlands

Hills1 has pointed out that in some conditions black holes in galactic nuclei would rapidly grow by disruption and accretion of stars thus producing Seyfert luminosities (>10<sup>43</sup> erg s<sup>-1</sup>). In this hypothesis only those galactic nuclei with a high central stellar density are susceptible to Seyfert pathology, and they evolve through only one Seyfert phase. Here, I suggest an alternative model for recurring activity in normal galactic nuclei based on the assumed presence of a massive nuclear black hole (  $10^7 M_{\odot}$ ) and the observation of a very clumpy distribution of interstellar gas in the inner 200 pc of our Galaxy. The system of massive molecular clouds with low net angular momentum could provide an 'accretion event' every 10 yr with a duration of ·10<sup>5</sup> yr. In such a picture, most spiral-galaxy nuclei evolve through recurring Seyfert episodes of rather short duration; the 1% accretion duty cycle is roughly consistent with the fact that a few per cent of all spiral galaxies are Seyferts2.

Molecular line observations of the central region of our Galaxy have revealed some  $10^7$ – $10^8\,M_\odot$  of interstellar gas in the inner 200 pc concentrated in massive molecular clouds (ref. 3 and refs therein). The 2.6-mm emission line of carbon monoxide has been particularly useful in mapping the distribution and kinematics of this molecular gas4.5. These studies show that there are essentially two kinematic groups of molecular clouds in the central region (Fig. 1). First, there are about 10 very massive clouds ( $\geq 10^6 M_{\odot}$ ) including the Sgr A and Sgr B2 complexes

which lie entirely at positive longitudes and within a projected distance of 150 pc from the centre. These clouds have line-ofsight velocities which are generally permitted in the sense of galactic rotation but which are much lower than the circular velocity at the sub-central point<sup>6</sup>. Either these clouds are presently stretched along the line-of-sight towards the centre (an unlikely and short-lived configuration), or they are close to the galactic centre but do not take part in systematic galactic rotation—they have a relatively low net angular momentum with respect to the centre.

The second group of clouds seems to lie in a single kinematically connected feature with high systematic non-circular motion—the 'expanding ring of molecular clouds' 5.7.8. This feature has been modelled by an expanding ring with a radius of 190 pc, a rotational velocity of 65 km s<sup>-1</sup>, and an expansion velocity of 150 km s<sup>-1</sup> (ref. 5). The total mass of this feature is between  $10^6$  and  $10^7 M_{\odot}$ ; therefore, the energy in expansion motion may be as high as  $10^{54}$  erg. It has been suggested that the non-circular motion associated with this feature may be due to elliptical streaming in the presence of a bar9. While expanding features at large distances from the centre (such as the '3-kpc arm') may result from such elliptical streaming, it is less likely that the high non-circular motions within 200 pc of the centre have such a gravitational origin. The gravitational field in the inner few hundred parsecs is dominated by the bulge component of the Galaxy, and bulges seem to be predominantly axisymmetric systems. Kormendy<sup>10</sup> has reported that bulges in some barred galaxies are slightly elongated perpendicular to the outer bar structure, but the apparent expansion observed both in the 3-kpc arm and in the molecular ring would require pronounced elongation of the bulge in the same sense as the outer bar structure<sup>11</sup>. Therefore it is plausible that the non-circular motion of the molecular ring results from a burst of high luminosity or mass ejection from a central object.

If the ring consisted of non-interacting test particles it would

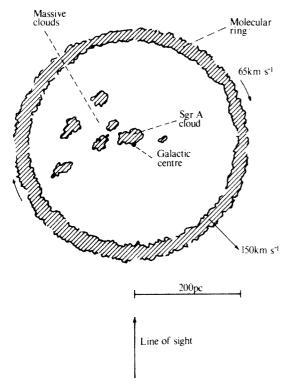

Fig. 1 The possible distribution of molecular clouds in the inner 200 pc of the Galaxy. The most massive clouds lie generally at positive longitudes and within the expanding 'molecular ring'. The Sgr A cloud may lie very close to the dynamical centre of the Galaxy.

oscillate between radii of 20 and 250 pc with a period of  $\sim 10^7$  yr. But as the ring consists of gas clouds it would not survive one such period because it would encounter gas with very different kinematics during an oscillation (that is, the massive molecular clouds closer to the centre). Therefore to maintain such high non-circular motions in the molecular cloud region (and CO line observations of the nuclei of other normal spirals do indicate the general presence of non-circular motions) a new outburst would be required every  $10^7$  yr or so, and this is the only evidence, albeit indirect, for recurring activity in our galactic nucleus. In terms of radiation from a central compact source, the centre of our Galaxy is certainly normal, but the high non-circular motions in the molecular cloud regions may be the hydrodynamic relics of short bursts of activity at the centre every  $10^7$  yr—relics which persist long after the other evidence of activity disappear.

We assume the presence of a black hole at the galactic centre with a mass  $M_h \sim 10^7 \, M_\odot$ . A compact object of this mass is entirely consistent with the velocity dispersion in the Ne II 12.8- $\mu$ M line emitting clumps in the inner 1 pc of the Galaxy<sup>13</sup> and might be identified with the milli-arcsecond radio source in this region<sup>14</sup>. There are about 10 massive molecular clouds in the inner 150 pc of the Galaxy with individual masses of the order of  $10^6 \, M_\odot$ . If we consider these 10 clouds to be particles randomly moving in a cylindrical volume ( $r = 150 \, \text{pc}$ ,  $h = 70 \, \text{pc}$ ) then a cloud will encounter the black hole on a time scale of

$$\tau \sim \frac{1}{n_{\rm c} v_{\rm c} \sigma_{\rm c}} \sim 10^7 \, \rm yr$$

where  $n_{\rm c}$  is the density of clouds,  $v_{\rm c}$  is the random cloud velocity ( $\sim 200~{\rm km~s^{-1}}$  to support the system of clouds against the galactic gravitational field) and  $\sigma_{\rm c}$  is the geometrical cross-section of a cloud determined from the observed cloud radius ( $\sim 20~{\rm pc}$ ). The clouds would also encounter one another on about the same time scale and, to maintain the random motions, the system of massive clouds would require an energy input similar to that required by the molecular ring.

A collision between a massive molecular cloud and a black hole could have spectacular consequences. The hole would accrete matter in a cylindrical column through the cloud; the radius of the column is essentially the Bondi radius:

$$r_{\rm a} = \frac{GM_{\rm h}}{v_{\rm c}^2} \sim 1 \text{ pc}$$

The fraction of the cloud mass accreted would be

$$\frac{M_{\rm acc}}{M_{\rm c}} \sim \left(\frac{r_{\rm a}}{r_{\rm c}}\right)^2 \sim 2.5 \times 10^{-3}$$

and if  $M_c \sim 10^6 M_\odot$  then the accreted mass is  $M_{\rm acc} \sim 2.5 \times 10^3 M_\odot$ .

Converting this mass to energy with an efficiency of 10% would produce a total energy of

$$E \sim 5 \times 10^{56} \text{ erg}$$

Only a few per cent of this energy need go into gas motion to account for the observed non-circular motions of the molecular clouds—both the systematic motion of the molecular ring and the random motion of the massive clouds. Assuming axisymmetric accretion and neglecting the effects of radiation pressure on the cloud, the time scale for accretion would be roughly the time during which the cloud is in contact with the hole:

$$t_{\rm a} \sim \frac{r_{\rm c}}{V_{\rm c}} \sim 10^5 \,\mathrm{yr}$$

If much of the energy came out in the form of radiation then the mean luminosity would be

$$L \sim E/t_{\rm a} \sim 10^{44} {\rm erg \ s^{-1}}$$

Therefore, every  $10^7$  yr, a cloud-black hole encounter would produce a burst of high luminosity lasting  $10^5$  yr; that is, a Seyfert nucleus would be turned on for  $\sim 1\%$  of the time.

An extremely clumpy distribution of low angular momentum gas in nuclear regions of spiral galaxies implies a highly variable accretion rate onto a massive nuclear black hole. The fraction of time in which accretion is going on is equal to the volume filling factor of the gas, and in the inner 200 pc of the Galaxy, this is a few per cent.

Hills¹ and Ozernoy¹⁵ have objected to the existence of a massive black hole in the galactic centre on the grounds that stars would be consumed too rapidly and thus produce a luminosity much higher than the observed upper limit to the luminosity of a non-stellar central point source. Assuming that the stellar density in the inner 1 pc core of the Galaxy is  $\sim 10^7 \, M_\odot \, \mathrm{pc}^{-3}$ , an upper limit of  $10^{40} \, \mathrm{erg \, s^{-1}}$  (ref. 16) on the luminosity of a compact source at the centre implies that the mass of a black hole must be less than  $10^4 \, M_\odot$ . It would be very fortuitous to see a black hole of this mass as the hole would grow to  $10^7 \, M_\odot$  in only  $10^9 \, \mathrm{yr}$ ; therefore a more probable upper limit to the black hole mass would be  $100 \, M_\odot$  (refs 1, 15).

However, these arguments only apply if the mass of the hole is substantially less than the mass of the stellar system. If the black hole has grown to  $10^7\,M_\odot$  and dominates the gravitational field in the 1-pc core of the Galaxy, then the rate of accretion of stars is very much lower again due to the slow rate of orbit diffusion in a system dominated by a point mass<sup>1</sup>. In other words, the critical radius for 'loss cone diffusion' exceeds the core radius of the nucleus. If f is the fraction of the core mass,  $M_c$ , in the black hole, then the rate at which the hole eats stars cannot exceed

$$\dot{N} = \frac{M_{\rm c}}{m_* \tau_{\rm R}} (1 - f)$$

where  $m_*$  is the mean stellar mass and  $\tau_R$  is the classical two-body relaxation time. With a 10% efficiency for converting consumed mass to energy, this implies that the luminosity due to consumption of stars is

$$L_{\rm N} = 4 \times 10^{42} \left(\frac{M_{\rm c}}{10^7 \, M_{\odot}}\right)^{1/2} \left(\frac{1 {\rm pc}}{R_{\rm c}}\right)^{3/2} (1 - f)^2 {\rm erg \, s}^{-1}$$

which is less than the observed limit if  $f \ge 0.9$ . A core mass of  $10^7 M_{\odot}$  and a stellar system mass of  $10^6 M_{\odot}$  (that is f = 0.9) are consistent with both the Ne II line observations of the core and the near-IR intensity of star light 13,18; therefore consumption of stars by such a massive black hole in our galactic nucleus does not violate observational constraints. For galactic nuclei in general, accretion of stars may have contributed to the rapid growth of nuclear black holes at earlier epochs and the higher frequency of active objects at large redshifts.

The problem with the efficiency of accretion in a cloud-hole encounter is that, due to radiation pressure on grains, the cloud may be blown away on first contact or before all the matter in the accretion column has been captured. However, because of density gradients within the cloud the captured material would probably possess some net angular momentum with respect to the hole. Therefore passage of the cloud would result in the formation of an accretion disk. In this case significant accretion and production of energy could begin after the passage of the cloud and take place on a longer time scale than that estimated above.

The probable formation of an accretion disk suggests an observational consequence for the model. As cloud-hole collisions are a stochastic process, the accretion disk axis will have no preferred orientation with respect to larger-scale galactic structure. The jets observed in radio galaxies 19 and the low-luminosity radio jets recently observed in Seyfert galaxy nuclei<sup>20</sup> are probably produced and collimated on the size scale of the accretion disk (« 1 pc), possibly along the rotation axis of the accretion disk<sup>21</sup>. Therefore, in the context of the present model, jets produced in the nuclei of spiral galaxies should have no preferred position angle with respect to the galaxy, and, from the preliminary observations, this seems to be the case<sup>20</sup>. The radio jets observed in Seyfert galaxies have linear extents of a few hundred parsecs to a few kiloparsecs; therefore, the collimating 'device' must be present and stable for time scales of at least 1,000 yr which again is consistent with the time scale of the accretion event.

Most of the energy produced in active spiral nuclei appears as electromagnetic radiation whereas the power of active elliptical nuclei goes into highly directed bulk gas motion (jets). This striking difference is probably related to the mode of accretion. Perhaps the distribution of gas in ellipticals is much less clumpy and the resulting accretion flow is smoother<sup>22</sup>. This would suggest that the position angle of elongated radio structure in ellipticals should be more correlated with the overall galactic structure<sup>23</sup> or at least with the larger-scale gas distribution<sup>24</sup>.

It would be of interest to observe the distribution and kinematics of dense gas in other spiral galaxy nuclei. In the context of this model, one would hope to observe the two species of nuclear molecular clouds in other galactic nuclei - clouds with systematic inflow or outflow and massive clouds with a low net angular momentum with respect to the galactic centre. The volume filling factor of such clouds should be of the order of a few per cent. High-resolution molecular line observations must await the development of millimetre-wave interferometers, although observations of the global kinematics of nuclear H II regions (the 'hot spot' nuclei) may also be relevant.

I thank R. D. Ekers and T. S. van Albada for their helpful comments.

## Soft X-ray imaging with a normal incidence mirror

#### James H. Underwood

Jet Propulsion Laboratory, California Institute of Technology, Pasadena, California 91109, USA

#### Troy W. Barbee Jr

Department of Materials Science, Stanford University, Stanford, California 94305, USA

By sputtering<sup>1,2</sup>, it is possible to make multilayered structures (layered synthetic microstructures or LSMs) with individual layers as thin as a fraction of a nanometre. Using these techniques, we have now made a multilayered interference mirror to reflect carbon K X rays ( $\lambda = 4.48$  nm) at normal incidence. The structure consists of 76 layers of tungsten of thickness 0.765 nm with layers of carbon (thickness 1.510 nm) interspersed, deposited on a (111) silicon wafer substrate. This LSM was formed into a concave mirror of radius ~1.1 m by bending the substrate, and used in an optical set-up to form images of grids illuminated by an X-ray source. The mirror was found to have a resolution of 5 lines mm<sup>-1</sup> and an efficiency, integrated over the C K band, of between 4 and 8%.

Until now, designers of X-ray optical instruments such as telescopes and microscopes have been forced to use mirrors operating at small glancing angles  $\theta$  ( $\theta$  = angle of incidence measured from the surface tangent)3,4. This is because the refractive index  $n = 1 - \delta$  of all materials is close to unity throughout the X-ray region, so that the fraction of the radiation reflected at the interface between a homogeneous material and air (or vacuum) is very low for values of  $\theta$  much greater than the critical angle  $\theta_c = \sqrt{2\delta}$ . Nickel, for example, has  $\delta = 2.4 \times 10^{-5}$  at a wavelength  $\lambda = 0.154$  nm,  $\delta \approx 1.4 \times 10^{-2}$  at  $\lambda = 4.48$  nm, and it can be seen that the corresponding reflectance values, roughly equal to  $\delta^2/4$  for normal incidence, are extremely small.

LSMs operate in a manner exactly analogous to multilayer dielectric coatings at visible wavelengths<sup>5</sup>, and can be used to

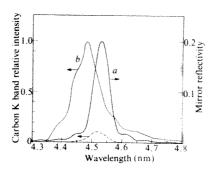

Fig. 1 Reflection of X rays by an LSM consisting of 76 layer pairs of tungsten ( $d_W = 0.765 \text{ nm}$ ) and carbon ( $d_C = 15.10 \text{ nm}$ ). Curve a (right-hand scale) is the reflectivity computed for the structure using the following optical constants: tungsten  $\delta = 1.10 \times 10^{-2}$ ,  $\beta = 1.29 \times 10^{-2}$ ; carbon  $\delta = 1.30 \times 10^{-3}$ ,  $\beta = 1.86 \times 10^{-4}$ . Curve b (left-hand scale) is the relative intensity of the C K-emission band8 The dashed curve (left scale) is the product of curves a and b. The area under this curve is 6% of that under curve b.

Fig. 2 Optical set up for normal incidence imaging with C K X rays.

increase the X-ray and UV reflectivity of surfaces. The resulting mirrors have numerous potential applications.

The simplest design is a periodic stack in which layers with a relatively high value of  $\delta$  (material A, thickness  $d_A$ ) are alternated with layers of low  $\delta$  (material B, thickness  $d_B$ ). Such a structure reflects X rays with intensity maxima at the Bragg angles  $\theta_m$  given by the relation

$$m\lambda = 2(d_A + d_B)\sin\theta_m \tag{1}$$

where m is the order of reflection. (Note that this simple relation must be corrected for the effects of refraction and absorption  $^{5.6}$ .)

We have constructed an LSM to reflect the K band of carbon ( $\lambda = 4.48 \text{ nm}$ ) in first order at normal incidence ( $\theta_1 = 90^\circ$ ), and have used it to obtain images of a grid illuminated with a carbon target X-ray tube. The structure consisted of 76 layer pairs of  $(d_{\rm W} = 0.765 \,\text{nm})$  and carbon  $(d_{\rm C} = 1.510 \,\text{nm})$ deposited on a silicon wafer with (111) surface orientation, 76.2 mm diameter and 0.38 mm thick. Figure 1 shows the reflectivity of the structure as a function of wavelength, computed using a standard multilayer program 5.6 using values of  $\delta$  and  $\beta$  (absorption index) given by Henke and Lee<sup>7</sup>. The relative intensity of the K-emission band of graphite carbon is also shown8. Although the peak reflectivity predicted for this multilayer structure is 20%, the layer period is not optimum for maximum reflectivity of C K radiation. The dashed curve in Fig. 1 is the product of the LSM reflectivity and the CK emission relative intensity, and represents an integrated reflectivity of ~6%. Note that any errors in the refractive indices will introduce uncertainties in the reflectivity calculations, affecting in particular the peak position.

The LSM-coated wafer was bent into a concave mirror of approximately spherical shape with a concentric-ring bending device patterned after that of Wassberg and Siegbahn<sup>9</sup>. This mirror was then set up on an optical bench in a vacuum chamber in the configuration shown in Fig. 2. The test object was illuminated from behind by a simple Coolidge-type X-ray tube with a colloidal graphite-coated target 1.25 mm in diameter. A special fine-grained film sensitive to soft X rays<sup>10</sup>, Eastman Kodak SO-212, was used as the detector. The film holder had a filter of 2-µm thick polycarbonate plastic foil coated with 120 nm of aluminium to exclude visible light.

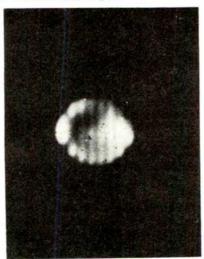

Fig. 3 Photograph of a 5 lines mm<sup>-1</sup> grid illuminated by a 1.25 mm diameter X-ray source. The non-uniformity of the image reflects the non-uniform pattern of X-ray emission by the target.

The apparatus was first aligned and focused using visible light to illuminate the test object. It was found that the silicon wafer could be bent to a radius of  $\sim 1$  m before severe aberrations set in. The object was set at a distance of 1,067 mm from the mirror and the film at a distance of 1,186 mm, with a resultant magnification of 1.11. As this off-axis configuration suffers from astigmatism, one-dimensional grids were used as targets and were set perpendicular to the plane of Fig. 2. The film was then set at position of the tangential focus.

Figure 3 is a photograph taken using C K X rays. The test object was an electroformed nickel grid with 0.1-mm bars separated by 0.1-mm spaces. The film was exposed for 1 h with

an X-ray source current of 2.5 mA at 1.5 kV.

To reduce aberrations, the mirror aperture was stopped down to 7.6 mm. With this aperture, the bright strips are easily resolved: the target period of 5 lines mm<sup>-1</sup> corresponds to about 40 arc s angular resolution. The resolution is limited by several factors, of which the most important is probably the imperfect optical figure of the mirror. A bending device of the kind used here bends even an isotropic lamina into only an approximation of a sphere, and in addition the wafer, being crystalline, tends to bend anisotropically and develop 'facets' that can be seen as a diffraction pattern in the visible light tests. Vibration of the optical bench, cantilevered in the vacuum chamber, is another possible source of degradation. Finally, the microscopic roughness of the layers themselves may cause scattering and degrade the resolution. This factor, which sets the ultimate limit of resolution that can be obtained with such a mirror, can be evaluated after the first two have been eliminated.

In this context, it is encouraging that tests with synchrotron radiation on similar LSMs yielded curves of reflectivity versus glancing angle in close agreement with those predicted from multilayer theory, indicating a high degree of layer perfection<sup>2</sup>. For the LSM described here, estimates of the reflectivity integrated over the C K band were made by densitometering an image and a piece of film exposed directly to the source behind a similar filter. The estimates lay between 4 and 8%, consistent with a 20% peak reflectivity and indicative of a close to perfect layer structure.

We conclude that normal incidence mirror elements for optical systems operating from a lower wavelength limit of 3-4 nm (soft X rays) out to 20 or 30 nm (EUV) are now feasible. Multilayer mirrors for these regions are being constructed both at Stanford University and at International Business Machines Corporation (see refs 11, 12). These optical systems have important potential applications in X-ray research and technology, and in some fields (for example, X-ray astronomy) may offer important advantages over glancing incidence optics, for example:

(1) The geometrical aberrations of normal incidence mirrors are much smaller, and the severe vignetting associated with glancing incidence mirrors is avoided thereby allowing a much larger field of view;

(2) Whereas a glancing incidence telescope reflects X rays of all wavelengths down to a certain cutoff value, the radiation reflected by an LSM is essentially monochromatic, so that auxiliary filters are not required;

(3) The collecting area of normal incidence optics is much greater for a given polished area of mirror (or substrate). Hence LSM optics, when fully developed, will probably be more cost effective.

The research at the Jet Propulsion Laboratory was supported by NASA under NAS7-100. The work at Stanford University was supported by Lawrence Livermore National Laboratories, and the NSF through the Center for Materials Research.

## Satellite measurements of H<sub>2</sub>O fluorescence in the mesosphere

#### J. R. Drummond

Department of Physics, University of Toronto, Toronto, Ontario, Canada M5S 1A7

#### C. T. Mutlow

Department of Atmospheric Physics, Clarendon Laboratory, Parks Road, Oxford OX1 3PU, UK

The concentration of water vapour in the mesosphere and above cannot be easily measured because the quantity of water is very small due to the low atmospheric density. Now, however, we report the observation of resonant fluorescent radiation from water vapour in the 50-95 km region by the Stratospheric and Mesospheric Sounder (SAMS) on Nimbus 7 satellite. Our preliminary data suggest that the mixing ratio of water vapour decreases with increasing height over this region with a value of  $\sim 1 \times 10^{-6}$  v/v at 75–85 km.

There are believed to be two water vapour sources in the upper atmosphere, both of which are subject to tropospheric influences. The first is direct injection by mechanisms at present poorly understood but probably involving the Hadley cell circulation in low latitudes and the 'tropopause gap' in mid-latitudes; the second is indirect injection through methane, also originating in the troposphere, which is then oxidized to carbon dioxide and water in the middle stratosphere. Evidence for the latter process is given by the apparent decrease in methane concentration at these levels and a simultaneous increase in water vapour concentration<sup>1</sup>

The predominant sinks (see reviews in refs 2 and 3) are re-exchange to the troposphere and photolysis in the upper atmosphere followed by the escape of the hydrogen produced

$$H_2O + h\nu \rightarrow OH + H$$
 (1)

Because water vapour influences upper atmosphere chemistry and hence the radiation balance and dynamics of the region, a knowledge of its concentration profile is important to our understanding of the upper atmosphere.

A multi-channel radiometer for composition sounding of the middle atmosphere, the SAMS<sup>4</sup>, was launched on the NIMBUS 7 satellite on 22 October 1978. Various channels on this instrument are designed to sense CO2, CH4, N2O, NO, CO and H<sub>2</sub>O. The instrument distinguishes radiation from a particular gas by 'pressure-modulation', an emission-sensing technique which has been described in detail elsewhere4

To increase the signal the atmosphere is viewed in the limb (Fig. 1) which has the advantage that emission observations can be made from as long a path through the atmosphere as possible against the cold radiation background of space. Such a limb path possesses an air mass about 70 times that in a vertical path above the lowest point of the path. The atmosphere's pressure profile and the geometry of the path both weight the material in the path strongly towards the tangent point giving good vertical resolution (~3 km for an infinitesimal field-of-view). In contrast, the horizontal resolution of a limb path is rather poor

The fundamental fluorescence mechanism for the 2.7-µm water vapour band is excitation by sunlight at 2.7 µm followed by radiative decay to the ground state by emission of a photon of

approximately the same frequency as that absorbed. However, competing effects can significantly influence or even dominate this simple process and of these effects three: collisional relaxation, indirect excitation and indirect radiative relaxation, need to be considered in detail. The details of the calculations will be published elsewhere.

The collisional relaxation rate of water vapour at room temperature has been measured<sup>5</sup> as  $1.1 \pm 0.4 \times 10^4$  s<sup>-1</sup> torr<sup>-1</sup> for collisions with  $O_2$ , and  $1.5 \pm 0.4 \times 10^4 \,\mathrm{s}^{-1} \,\mathrm{torr}^{-1}$  for collisions with N<sub>2</sub>. The radiative relaxation rate is 79 s<sup>-1</sup>

The unusually small ratio of the radiative to the collisional relaxation rate at one atmosphere ( $\approx 8 \times 10^{-6}$  atm compared with, for example, the  $\nu_3$  (4.3  $\mu$ m) band of CO<sub>2</sub> for which the ratio<sup>6</sup> is  $2.6 \times 10^{-4}$  atm) may be the most significant fundamental problem with this method of concentration measurement. It implies that the level at which collisional relaxation becomes important occurs very high in the atmosphere at a level of  $\sim$  90 km and the region of interest, the mesosphere, is a region of competition between collisional and radiative relaxation processes.

As the emission from the atmosphere in these conditions is almost entirely non-thermal it is necessary to compute the source function,  $J_i$ , at all levels before calculating the observed signal. Although in a general analysis account must be taken of radiative exchange within the atmosphere, in this case secondary scattering can be neglected and the source function for a planeparallel atmosphere written in the form:

$$J_{1} = n_{1}B(\tilde{\nu}_{0}, T_{1}) = \frac{\beta_{1}F_{s}}{1 + \rho_{1}} + \frac{B(\tilde{\nu}_{0}, T_{1})\rho_{1}}{1 + \rho_{1}}$$
(2)

Suffix 1 refers to the atmospheric layer,  $\tilde{\nu}_0$  is the central wavenumber of the band,  $T_1$  the kinetic temperature, B the Planck function and  $F_s$  the solar flux.  $\rho_1$  is the ratio of the collisional to radiative relaxation times, which depends on temperature and pressure.  $\beta_1$  accounts for radiative transfer within layers, absorption in the atmosphere above the layer and the structure of the 2.7- $\mu$ m band;  $n_1$  is the factor by which the source function, J, exceeds the Planck function, B. The source function shows the same spectral dependence as the Planck function at temperature  $T_1$ .  $\beta_1$  is computed from a knowledge of the spectral line distributions using the AFGL line data compilation<sup>7</sup>.

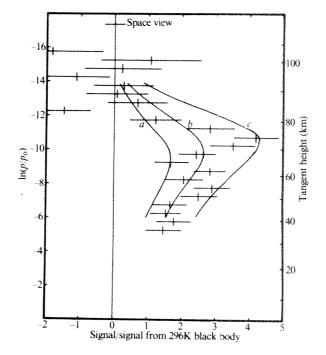

Fig. 1 The viewing geometry of the experiment. To keep the solar zenith angle to small values, data are only collected in the equatorial region. The satellite orbit height is ~950 km.

The most serious error in this equation probably arises from neglecting excitation in the 2.7-µm levels due to cascade decay from higher quantum levels, notably 101 and 011.

After computation of the source function the radiance measured by the instrument can be computed from a knowledge of the instrumental response function. For a pressure modulator radiometer this is a complicated function related to the lineshape and is non-zero only near the centres of spectral lines4. Because of this exact correlation between line positions and the instrument response function, the relative velocity of the atmosphere and the satellite must be included in the calculation. The instrument views the atmosphere in a direction perpendicular to the satellite velocity vector so that the only shift is due to the Earth's rotation. This induces a relative shift of about one doppler width in the signals and a 20% decrease in the observed signal.

Despite the enhanced emission due to fluorescence, the signals detected by the instrument are extremely noisy. This is due partly to the low density in this region and partly due to the apparently low water concentrations at these levels. Data for fluorescent measurements can only be taken when the satellite instrument is turned on, in a suitable operating mode and viewing the correct tangent height range<sup>4</sup>. The averages shown in Fig. 2 use all the available data from day 93 to day 103 1979, each point representing an average of 1,000-4,000 individual 1.8-s integrations. To eliminate effects caused by variations in the solar zenith angle, data are restricted to ±45° on either side of the equator. The vertical profile is quantized in units of 0.5 scale height ( $\approx$ 3 km). The nightside data were similarly analysed to demonstrate that this is a fluorescence phenomena and the signal in that region is zero as expected. The instrument is calibrated using the two-point method with a space view for zero signal and an internal calibration black body to provide a known radiance. The calibration procedure is more efficient than atmospheric viewing as the exact space angle is not critical and a reasonable instrument calibration can be achieved in ~36 h operating time.

The calculated signals shown in Fig. 2 have been computed from simple profiles of constant concentration with height using the data above for the collisional relaxation rate, assumed to be independent of temperature.

The most striking feature of the data is that they seem to predict a low concentration of water vapour in the upper

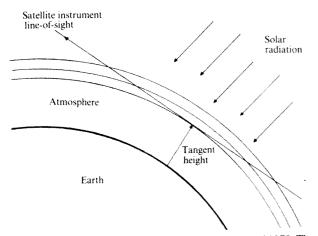

Fig. 2 Measurements and calculations for the spring of 1979. The three solid lines are calculated signals for constant volume mixing ratios of: a,  $5 \times 10^{-7}$ ; b  $1 \times 10^{-6}$ ; c,  $2 \times 10^{-6}$ . The data are shown by the crosses. The horizontal error bars are due to instrument noise and the vertical error bars to the vertical resolution of the averaging procedure. The zero radiance calibration point is established by periodically using a tangent height of >130 km, effectively eliminating all the atmosphere from the ray path. The standard deviation of the space view is shown as an isolated point at the top of the diagram. The vertical axis is  $ln(p/p_0)$  or the negative of 'scale height'. The tangent height scale on the right was constructed using an equatorial standard atmosphere for March.

mesosphere. The shape of the profile is fairly insensitive to the concentration of water vapour in the lower mesosphere and therefore the profile is reasonably consistent with either a constant, low concentration of water vapour or, more probably, a decreasing volume mixing ratio with height. Thus the shape of the profile is more consistent with that of Swider and Narcisi<sup>8</sup>, who also show a decrease with height, than that of Arnold and Krankowsky9, who show a constant mixing ratio with height.

Efforts are now being made to improve the quality of data reduction to obtain better information on the vertical distribution of water vapour as well as its seasonal variations.

## **Bond-lengths, bond angles** and transition barrier in ice Ih by neutron scattering

W. F. Kuhs & M. S. Lehmann

Institut Laue-Langevin, 38042 Grenoble Cédex, France

Although several studies 1.2 of ordinary ice (Ih) have established its nearly perfect oxygen arrangement and the statistical distribution of hydrogen among two symmetrically equivalent sites (the 'half-hydrogen' model3), several fundamental problems remain. The O-H bond length found in ice Ih is considerably larger than in other polymorphs of ice determined precisely4 and many arguments have been put forward against the value observed<sup>5,6</sup>. Similarly, the tetrahedral H—O—H bond angle in ice Ih differs considerably from the value observed in the vapour phase, and this led Chidambaram7 to propose a bent hydrogen bond model which further splits the atom positions, and which has not yet been verified. Finally, the mean shape of the double potential governing the atom distribution and the barrier governing the mobility still remain to be evaluated. We show here how high-precision, short-wavelength neutron diffraction data from ice Ih can be used to evaluate the molecular structure and atomic density distribution at 60 K. The unusually long -H distance is confirmed, but there is no evidence for bent hydrogen bonds. Indeed the hydrogen atom density distribution is well described by a librational motion of the hydrogen atom around the oxygen. The mean barrier height between the 'halfhydrogen' atom positions was obtained from the scattering density as 0.012 eV, which implies that the zero point motion is of high importance for the proton exchange at low temperatures.

Measurements were done at the four-circle neutron diffractometer D9 of the Institut Laue-Langevin using a wavelength of 0.7107(5) Å on a pure specimen of 6.5 mm<sup>3</sup> cut from a larger sample (supplied by A. Chaillou, Laboratoire de Glaciologie, Grenoble). The temperature was maintained using a closed loop refrigerator and data were recorded with the  $\omega$ - $2\theta$ step-scan technique. The intensities were reduced to structure factors using standard techniques8, and corrections made during the analysis for absorption9, anisotropic thermal diffuse scattering10 and anisotropic extinction11. The cell dimensions used in

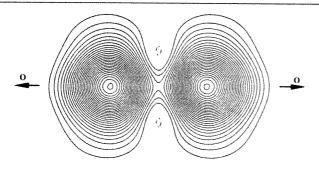

Fig. 1 Probability density map of H2 in the (0001) plane as described by harmonic and anharmonic terms up to sixth order.

the calculations are taken from the literature <sup>12</sup>: a = 4.497(1), c = 7.321(2) Å  $(1 \text{ Å} = 10^{-10} \text{ m})$ . A total of 1,887 reflections were recorded up to  $\sin\theta/\lambda = 1.07 \text{ Å}^{-1}$ , and they gave 288 reflections after averaging. The agreement factor among symmetry-related squared structure amplitudes was 0.041, and 222 of the final reflections had  $I \ge 3\sigma(I)$ .

From the data, different structural models were tested using crystallographic least-squares procedures. All the calculations were done using the Prometheus-system<sup>13</sup>, which allows incorporation and refinement of higher-order thermal tensors. The 'half-hydrogen' model was refined successfully to a weighted reliability factor  $R_{\rm w}$  of 0.013. Introduction of anharmonic thermal parameters (using a Gram-Charlier expansion of the harmonic trivariate gaussian probability function<sup>14</sup>) improved the agreement to  $R_{\rm w} = 0.012$ . To estimate the double well potential correctly from the scattering density, a calculation was carried out with the hydrogen atom located midway between the oxygen atoms, that is fixed on the saddle-point of the doublewell potential. If terms in the expansion up to the sixth order were included the refinements were successful. Only one hydrogen atom at a time was refined this way, and the two agreement factors obtained for H1 and H2 were 0.015 and 0.018, respectively. The results of all refinements show clearly the disorder of the hydrogen atoms. Figure 1 shows the atom probability density derived from the above refinements.

The results of a neutron diffraction experiment give scattering densities averaged over time and symmetry-related space in the crystal. If the molecular structure is represented conventionally by atoms undergoing harmonic motions, then observed interatomic distances must be corrected for the curvilinear relative motions of the atoms. This correction is not straightforward, as the curvilinear motion cannot be separated from the other atomic motions. However, using an anharmonic probability density function description of the hydrogen atoms allows a direct calculation of the true mode-mode distances as well as their, possibly different, equilibrium-equilibrium distances. The resulting bond lengths and bond angles given in Fig. 2 confirm the earlier observations, and indicate fundamental differences between the electronic hybridization state of ice Ih and that of

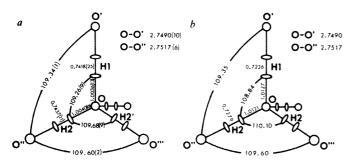

Fig. 2 a, The mean-mean bond distances and angles in the harmonic approximation. The errors (given in brackets) include the errors of the lattice constants. b, The mode-mode bond distances and angles of the anharmonic treatment. The corresponding equilibrium-equilibrium values are almost identical at a temperature of 60 K. The errors are hard to calculate and therefore not given.

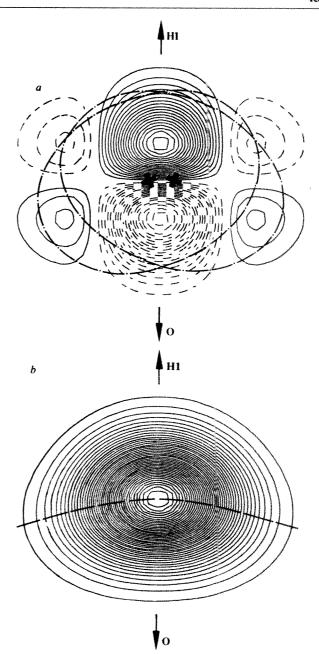

Fig. 3 a, Skewness-map of H1 in the  $(10\bar{1}0)$  plane. Solid contours show positive, dashed contours negative modifications of the harmonic (gaussian) density distribution. The dashed-dotted lines give the equiprobability contours of two atoms of the bent-bond model; their equilibrium sites (exactly in-plane) are marked by crosses. b, Total probability density map of H1 in the same (10\bar{1}0) plane as Fig. 3. The librational motion is clearly visible; the dashed line shows the trajectory of this motion. Note the similarity of this density distribution to a superposition of the bent-bond model densities given in Fig. 3a.

other ice phases studied. This could probably be caused by the complete hydrogen disorder coupled with the very low transition barrier as discussed below.

Further structural refinements were done testing the 'benthydrogen bond' model<sup>7</sup> by introducing the corresponding sixfold hydrogen splitting. The resultant agreement factors were comparable with those for the refinements of the anharmonic model. The outcome is, however, less favourable for two reasons. First, a comparison using Hamilton's *R*-factor test<sup>15</sup> and starting in both cases from the harmonic model showed the improvement to be highly significant on the 0.005 level for the anharmonic model (one parameter added), whereas the benthydrogen bond model improvements were only significant on the 0.05 level with three parameters added. Second, one would

Table 1 Root-mean-square displacements of the harmonic model

		Orientation of principal axes				
Atom	r.m.s.d. (Å)	Angle with $a_1$	Angle with $a_2$	Angle with c		
0	0.1166 (4)	90.0	90.0	0.0		
	0.1176(11)	warming.	and the same of th	90.0		
H1	0.1335 (12)	90.0	90.0	0.0		
	0.1787(8)	-	*******	90.0		
H2	0.1360(11)	90.0	36.3	111.5		
	0.1762 (11)	90.0	108.5	158.5		
	0.1801 (11)	0.0	120.0	90.0		

expect the hydrogen probability distribution to show signs of modes, or at least a positive modification in the direction of the bending of the bond, and this is not the case. Figure 3a shows the deformations from harmonicity found for one of the hydrogen atoms with the equiprobability contours of the bent-bond model superimposed. The main feature in the deformation density is clearly derived from the librational motion of the atom, whereas in the direction of the expected bending the density is merely slightly modified and as expected in the opposite way. Thus the librational motion has a slightly preferential orientation only and can be described as a motion on the surface of a sphere. A section through the total density is given in Fig. 3b. The bentbond model resembles this motion enough to mimic the density at the price of placing fractional atoms on weakly marked saddle-points in the density. The bond angle of 105° can therefore be ruled out noting, however, that the largest motion is in the 'soft' direction corresponding to the proposed bend.

The atomic root-mean square displacements (r.m.s.d.) are given in Table 1. The expected stretching frequencies calculated from the thermal motion in the harmonic approximation are  $950(38) \text{ cm}^{-1}$  for libration and  $3,780(380) \text{ cm}^{-1}$  for O-H stretch, which agree well with other experimental values10

There was some evidence for a measurable probability density between the 'half-hydrogen' positions in the Fourier maps given by Petersen and Levy1. This is confirmed by the present calculations, and clearly observable in Fig. 1. The density at the saddle-point is about four times the estimated error, and corresponds to a barrier height of ~0.012 eV for both hydrogen atoms. These low barrier heights imply both that even at low temperatures the transition frequency is high and that the zero-point motion must be of importance in the proton transfer process. From the full mean potential as derived from diffraction data one can estimate transition probabilities and lingering times, and this work is now in progress together with further studies at other temperatures and of the deuterated species.

This study confirms the earlier observations 1,2 of the geometry of the water molecule, namely that the H-O-H angle is 5° larger than in the vapour phase, and that the O-H bond is considerably larger than the vapour-value of 0.97 Å (ref. 6). Whereas it is quite common to observe increases of 2-5° in the H-O-H angle in hydrated compounds, an O-H bond length in water larger than 1.00 Å is highly unusual. As argued by Whalley6 this would correspond to a storage of elastic energy which is one-fifth of the sublimation energy or several times larger than the energy difference between ice Ih and ice II (ref. 4) or ice IX (ref. 5), which have both been observed to have mean O-H bond lengths of 0.98 Å. Likewise<sup>6</sup> the observed change in frequency for the O-H stretch does not reflect the large change in the bondlength when compared with similar results in ice II and ice IX. The present measurements of the mean structure cannot by itself be used to give an explanation of these differences, but some indications can be sought from the detailed description of the atomic density distribution (see Fig. 1). Here there is clearly a finite probability of finding H in the middle of the bond. This would correspond to a transition frequency not much smaller than the stretching frequency. In the transition state, because of cooperativity (see, for example, the ice rules3), one hydrogen atom will be approaching oxygen while another is leaving and this will create an entity with an electronic state much different from normal H<sub>2</sub>O, but undoubtedly with all O—H bonds longer than in water. The diffraction result is a sampling over all states with sampling times shorter than the transition time, and the result is an observed elongation of the O-H bond. Both ice II and ice IX are ordered structures, and one would thus, even without a detailed analysis of the scattering density, not expect a similar behaviour. Only very extensive quantum chemical calculations and lattice dynamical estimates would give the actual increase in bond length and indicate why the effective transition barrier is so low. Based on the present measurement we can only state that there seem to be coherence between the observation of the long O-H bond distances and the low barrier.

The list of structure factors is available from the authors.

## The role of liquid halogen in the reaction of crystalline KBr with gaseous Cl2

## Andrew K. Galwey & Làszlò Pöppl\*

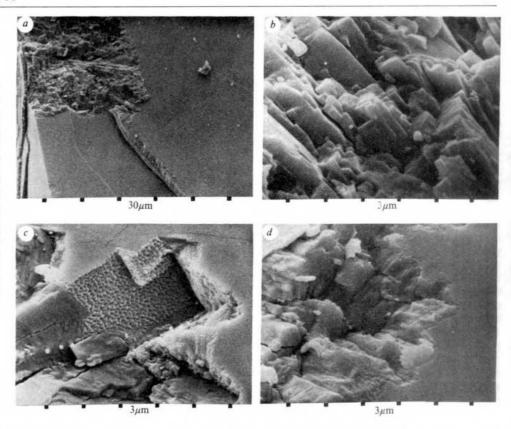

Chemistry Department, The Queen's University of Belfast, Belfast BT9 5AG, UK

Problems in formulating a mechanism<sup>1,2</sup> for the reaction of crystalline KBr with gaseous  $Cl_2$  (KBr(s) +  $Cl_2$ (g)  $\rightarrow$  KCl + BrCl) (a nucleation and growth process) and the role of dislocation proliferation3 in promoting interface advance have been widely discussed. The evidence that local textural changes, in the vicinity of an active reaction interface, could be observed microscopically prompted us to examine the system using scanning electron microscopy. From these textural observations together with kinetic and other measurements, we conclude that liquid halogen (Cl2, BrCl and Br2) and dissolved intermediates, contained within the pore system permeating the solid product assemblage (the nucleus), are essential participants in the chemical change. We believe that reactant KBr dissolved in condensed halogen retained in pores at the reaction interface then interacts with chlorine to form polyhalide intermediates (probably including [BrCl<sub>2</sub>]") subsequently depositing KCl product. Microscopic observations show that the nucleus is composed of KCl plates, penetrated by narrow (~0.2  $\mu m$ ) channels. This reaction model could be applicable to other systems, as previous discussions of solid state nucleation and growth processes have only rarely explicitly considered the possible participation of an intranuclear liquid and dissolved intermediates4

A feature of the reaction not emphasized in previous reports<sup>1-3</sup> was the invariable and strongly developed red-brown colouration of the product nuclei. This is important evidence of the retention of liquid bromine (and BrCl) within the product

Fig. 1 Scanning electron micrographs of potassium bromide crystals after partial reaction in chlorine, cleaved in the (100) direction to reveal internal structures. Scales refer to spacing points at the lower edge. a, Cleavage across a nucleus; the unreacted crystal is smooth, the product is an irregular assemblage of small crystallites. Interface advance occurs in directions of principal axes. b, Texture of product within growth nuclei: KCl crystals and channels are oriented in the (111) direction (photograph edges are oriented in (100) and (010) directions). c, Details of interface after reaction at 273 K. d, Details of interface after reaction at 325 K.

assemblages which, on standing in air or vacuum at ambient temperatures, volatilized as a brown, pungent gas. The free halogen content of recently reacted salt, which we measured by titration was 3% Br<sub>2</sub> by weight, though values varied between 1 and 5% depending on reaction conditions. This quantity of liquid would occupy perhaps one-tenth of the 13% volume diminution resulting from replacement of reactant KBr with product KCl. More importantly, this volume of gaseous halogen would not be accommodated within the pore space of the residual product. Differential scanning calorimetric measurements for the freshly reacted salt, over the 310–600 K temperature range, gave only a single small broad endotherm at 350–390 K, quantitatively consistent with the evaporation of this small quantity of Br<sub>2</sub>, if present as a liquid. This is strong evidence of halogen retention during reaction.

Rate measurements were made using crystal fragments  $(0.5 \times$ 5×5 mm) freshly cleaved from a single KBr block (Specac Ltd). The vacuum apparatus used was similar to that described in ref. 5. The KBr reactant specimen was maintained at constant temperature (±0.5 K) and, after initial evacuation (10 min at 10<sup>-5</sup> torr), a known pressure (50, 100, 200 or 400 torr) of chlorine reactant was admitted. The cleaved KBr surface was observed with an optical microscope. Small nuclei were often approximately circular but after growth became square with bounding edges oriented parallel with the principal crystal axes. Predominantly diagonal cracking developed during continued growth. The red-brown colouration of the nuclei was usually most intense in the vicinity of the active reaction interface. Edge lengths of these square nuclei were measured at suitable time intervals to determine rates of interface advance. These were invariably constant-typically 0.02 µm s<sup>-1</sup> at 283 K. Rates increased with temperature by a factor of ~10 between 273 and 350 K. Growth rates for different nuclei on the same crystal face and for concurrent reactions within the same environment showed close agreement. There were, however, appreciable differences in growth rates of nuclei between successive experiments proceeding in nominally identical conditions. Rates of reaction increased with increase in the prevailing chlorine pressure. After interruption of reaction by evacuation, or a sudden reduction of chlorine pressure, the advance of the interface halted before continuation of reaction. We attribute

this to immediate volatilization followed by slow replacement of the liquid halogen within the nucleus.

Previous work<sup>1</sup> has shown that induction periods preceding the development of growth nuclei were considerable (500–5,000 min at ~290 K) as were the subsequent acceleratory nucleation processes (perhaps half as long). The equation  $(N = At^3[1-\exp{(Ct)}])$  has been used<sup>2</sup> to express the variation in the number of nuclei (N) present with time (t) (A and C are constants). We confirm the earlier observation<sup>2</sup> that nuclei are preferentially developed at sites of surface damage. We account for these kinetic characteristics by identifying potential nuclei as the finest superficial cracks within which there is condensation of halogen, BrCl and Br<sub>2</sub>, released by slow reaction of chlorine with reactant surfaces, until a liquid droplet is formed. The subsequent promotion of reaction as a growth nucleus increases the availability of bromine, so accelerating the activation of further nucleus-forming sites.

From the suggestion<sup>2</sup> that the nucleation process is catalysed by specific catalysts, we reasoned that such a substance would be a covalent liquid, capable of dissolving halogens at reaction

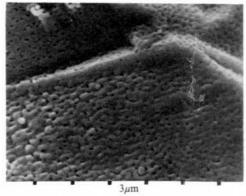

Fig. 2 Scanning electron micrograph of potassium bromide surface after cleavage followed by exposure to saturated bromine vapour for 5 min at 288 K. Cleaved surfaces were planar with step edges and exposure to bromine vapour (or liquid) caused modification including recrystallization which became more extensive after longer times of exposure.

temperature (~270-370 K) and also form a weak complex or double salt with KBr and with KCl. Tin (IV) chloride possesses these properties and a few small particles of metallic tin (20 µg) (rapidly chlorinated to SnCl4 in reaction conditions) on the reactant KBr surface reduced the induction period to nucleation at 300 K from several days to <3 h. This catalysis by liquid SnCl. is further evidence for the participation of a liquid phase in this reaction. GeCl4 and PbCl4 similarly promoted the generation of growth nuclei.

Studies using the optical microscope were supplemented using the scanning electron microscope. Surfaces only could be investigated by this technique, though information concerning internal features of partly reacted crystals was obtained through the examination of surfaces exposed by cleavage after reaction. As reacted surfaces were particularly sensitive to water vapour, atmospheric exposure was minimized. Replication<sup>7</sup> of surfaces and pore structures of developed nuclei was not possible as textural reorganization of the reactant occurred in the solvents used.

Typical internal features of growth nuclei, as revealed by cleavage, are shown in Fig. 1a-d. In Fig. 1a the featureless area of unreacted KBr contrasts with the roughened texture of the section across the assemblage of product KCl crystallites. The rectangular development of nuclei is also evident, resulting from equal rates of interface advance in the (100), (010) and (001) directions. The higher magnification in Fig. 1b shows typical rectangular crystallites of product with intercrystalline channels oriented in the (111) direction (photograph edges are aligned with the principal axes). These channels contain liquid halogen during reaction, provide access for inward diffusion of Cl2 to replace that which has reacted and permit removal of product Br<sub>2</sub> and BrCl. Characteristic textures of the irregular nucleus boundaries, the advancing reaction zone, are shown in Fig. 1c, d. There was no evidence that cracks penetrated the KBr beyond the nucleus. The etched appearance of the zone of active interfacial reaction (the centre of Fig. 1c) resembled textures developed on immersion of KBr in liquid Br<sub>2</sub> or on exposure to saturated vapour pressure of the gas; compare Fig. 1c with Fig. 2, which is a cleaved surface after exposure to saturated bromine vapour for 5 min at 288 K. Details of such surface retexturing varied with exposure times and temperatures. Retained bromine, released from nuclei on cleavage, could cause surface retexturing of adjoining zones of unreacted KBr. This again is evidence that liquid participates in the chemical change. Comparisons of Fig. 1c, d, for crystals reacted in 200 torr Cl<sub>2</sub> but at 273 and at 325 K, show that larger crystals of product were developed during the lower temperature reaction.

We conclude that the participation of a liquid phase in the interfacial processes provides a more satisfactory explanation than alternatives, such as strain, for several characteristic features of behaviour, such as the temporary cessation of interface advance after rapid gaseous reactant withdrawal, the activity of a liquid catalyst in accelerating the nucleation step and reactant textures at the interface. Furthermore, this involvement of homogeneous reactions within liquid generated in the vicinity of the interface is of wider interest because many studies have not characterized the chemical steps occurring within the reactantproduct contact zone, which are often experimentally inaccessible. Some aspects of the forms and functions of nuclei have been discussed recently<sup>5,8</sup> but more often it has been assumed<sup>4</sup> that solid products do not impede the escape of volatile products. Much recent work has related rate data to the progressive changes of interface geometry as reaction develops. The identity of a rate limiting process is sometimes inferred from the magnitude of an apparent activation energy4. The participation of a liquid localized and temporarily retained at a specialist structure within the nucleus offers an attractive explanation of the reactant species mobility that may be required to permit a bond redistribution step. Furthermore, interface processes are often accompanied by recrystallization and retexturing which similarly may proceed more readily in the presence of a liquid. The elucidation of the chemistry of interface processes is a fundamental step in identifying the factors which control the reactivities of solids.

A.K.G. thanks S.R.C. for an equipment grant and L.P. thanks the Leverhulme Trust for a Visiting Fellowship. We thank Mr. R. Reed for assistance in obtaining the electron micrographs.

Palacopoles from the Keweenawan (1,200-1,000 Myr) rocks of the Lake Superior region form the western and eastern arms of the 'Great Logan Palaeomagnetic Loop'<sup>1-5</sup> (Fig. 1s). This is defined by both normal (N) and reversed (R) poles which are the consequence of at least two geomagnetic reversals<sup>4,4,7</sup>. The younger one  $(R \rightarrow N)$  has been detected throughout the Lake Superior region from various rock types. 1-4 The older reversal  $(N \to R)$  is only recorded in the lowermost Keweenawan lavas in the southern part of the lake. Wherever found, the reversals depart from the 180° symmetry (Fig. 1a)<sup>2-4</sup>. Due to these asymmetries, the Logan Loop has large segments that are devoid of data and thus the geophysical interpretations of the Loop (or 'hairpin') critically depend on the cause of the reversal asymmetry. Four models. (secondary component, apparent polar wander. Wilson's dipole offset. and non-dipole field configuration. have been put forward to explain the asymmetry. metries. Here we demonstrate that the two-dipole field configuration model can explain the reversal asymmetries and discuss the global effects of this model in the light of worldwide late Precambrian palaeomagnetic data.

First we assume that the geomagnetic field during Keweenawan time consisted of an axial geocentric dipole (main dipole,  $\dot{M}_{N,R}$ ) and an axial offset dipole ( $\dot{m}$ ) (see also refs 12–14). The geocentric dipole has two polarity states, normal and reversed (Fig. 2). The magnetic dipole moments during these states are equal  $(M_N = M_R)$  but antiparallel  $(\tilde{M}_N, \tilde{M}_R)$ . The field of the main dipole is disturbed by the persistent non-dipole (Nd)field component, the source of which is represented as the offset dipole  $(\vec{m})$ . The perturbing field represents a long-term zonal average of the Nd field  $^{0.13}$ . An asymmetric reversal will take place, when the geocentric dipole reverses while the offset dipole retains its constant polarity.

In the first case the offset dipole with normal polarity  $(\vec{m},\vec{M}_N)$ is located at the northern core-mantle boundary (Fig. 2a). If the ratio of the dipole moments (m/M) is 0.19, the inclinations at the Lake Superior area with a palaeocolatitude 53°, will be  $I_{\rm R} = -71^{\circ}$  and  $I_{\rm N} = 42^{\circ}$ , corresponding to average values observed from Middle/Lower Keweenawan data (Table 1).

In the second case (Fig. 2b), the offset dipole of reversed polarity is located at the southern core-mantle boundary. If the ratio of the dipole moments is 1.20 (that is m > M), the inclinations at the Lake Superior area with palaeocolatitude 46° will be the same as in case I. However, in this case the ratios of the global average of the Nd field to the dipole field (d) are

unrealistically large (Nd/d = 14 (R polarity), Nd/d = 1.5 (N polarity)), whereas in case I the ratios (Nd/d = 0.56 (R polarity), Nd/d = 0.38 (N polarity)) are only about twice as high as those for the past 100 Myr (ref. 15). Note that due to axial symmetry of these models, the declinations have the observed 180° shift in both cases as observed (Table 1).

If the main dipole now makes another reversal  $(R \rightarrow N \rightarrow R)$  and so on), the inclinations will be successively asymmetric as observed in the Mamainse Point area<sup>5</sup>, provided that the offset dipole retains its polarity. Because the palaeopoles are calculated by assuming an axial geocentric dipole field, the reversed

poles (with steep negative inclinations) will be nearsided and the normal poles (with shallow positive inclinations) farsided with respect to the sampling site (Fig. 1a). The true Keweenawan palaeopoles, assuming that no polar wander has taken place across the reversal, will be the same for normal and reversed epochs and lie roughly in the middle of observed poles, 53° (case I) or 46° (case II) from the sampling site. The true poles (TKM, TKL) according to our model I are shown in Fig. 1b.

If the offset dipole (in) is of reversed polarity (case I) or of normal polarity (case II), the two models produce steep normal and shallow reversed inclinations. The distribution of

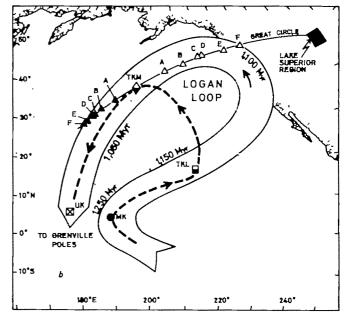

Fig. 1—a, The Great Logan Palaeomagnetic Loop as recorded in late Precambrian Koweenawan rocks from the Lake Superior region of North-America. Only such Koweenawan data, where both normal (closed symbols) and reversed (open symbols) polarities are available, are indicated. The numbers and letters refer to Table 1. The great broken circles best fit the observed poles. The swath width (10°) corresponds to an average confidence value ( $\alpha$ 95) for an individual pole determination. MK, the average pole for the Mackenzie igneous interval (1,250 Myr); UK, the average Upper Koweenawan pole (1,000 Myr). For data and references, see Table 1 and ref. 7. b. The great circles and A-Frepresent the generated APW segments produced by the two-dipole model in Fig. 2a when the dipole-moment ratio m/M values from 0.10 to 0.30 (A, 0.10; B, 0.15; D, 0.20, E, 0.25 and F, 0.30). The point C (m/M = 0.19) corresponds to the average Middle/Lower Koweenawan asymmetry with  $I_R = -71^{\circ}$ ,  $I_R = 42^{\circ}$ , respectively (Table 1). The poles TKM, (TKL) represent the true average Middle/Lower, (Lowermost) Koweenawan poles corrected for the two-dipole model. Note that there is no particular chronological order of poles from A to F m both polarities and the model allows APW 'jumps' back and forth along the generated polar wander segment. Such oscillatory APW movement has been observed in both Koweenawan<sup>5,7</sup> and coeval Grand Camyon<sup>7,26</sup> data.

<sup>†</sup> dp, dm = 95% confidence limits for the pole (single study); (a95) = 95% confidence circle for the pole (several studies combined). See ref. 7 for other refs

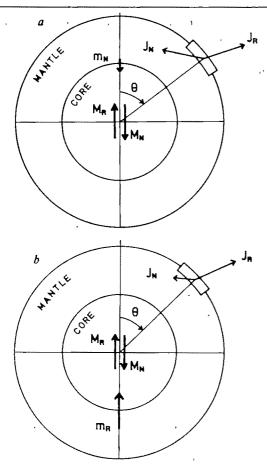

Fig. 2 Coaxial two-dipole geomagnetic field configurations which are capable to explain the late Precambrian Keweenawan asymmetries at the Lake-Superior area. a, Case I model; b, case II model (see text).

palaeomagnetic directions of NE-SW trending late Gardar dykes of Greenland 16 may be interpreted in this way.

The distributions of Keweenawan poles in Fig. 1a, fit quite well onto two great circles (western and eastern), which intersect near the sampling site. This type of pole distribution is in accordance with the axial offset dipole models 7,12. Therefore, the great depth extent of the Logan Loop may be a signature of the oscillation of the m/M ratio rather than plate motion as previously thought<sup>1-4</sup>. If we consider case I and allow the ratio m/M to vary 0.10 to 0.30 in steps of 0.05 while all the other variables remain fixed, the theoretical and purely apparent great circle polar wander segments can be generated as shown in Fig. 1b. The observed Middle/Lower Keweenawan poles (western arm) in Fig. 1a agree well with the theoretical poles. Note that the generated path segments of reversed and normal poles differ (Fig. 1b) because the function which maps the palaeomagnetic directions to the palaeopoles depends on the inclination, so that a longer segment of the palaeopoles is obtained for steeper inclinations1

In our new interpretation, the size and depth of the Logan Loop are drastically reduced. Plate motion during the Keweenawan is, however, still recognized in the new loop (Fig. 1b). The APW segments joining the Mackenzie pole (MK; 1,250 Myr) and the true Keweenawan poles (TKL, TKM) to the upper Keweenawan (UK, 1,000 Myr; ref. 7) and Grenville poles (950 Myr; ref. 18) probably represent the real paleomagnetic signature of the plate motion during the Keweenawan.

However, along the segment from the true normal pole (TKM) to the 'oscillatory' pole F (normal polarity), both plate motion and dipole oscillation are likely to cooperate in producing the APW swath. Note also that the reduced size of the Logan Loop decreases the previously proposed high APW rate.

Without the possibility of testing new models, they would be only ad hoc Nd explanations<sup>19</sup>. Three independent observations are available to test the credibility of our models.

The first test involves consideration of the distribution of the poles. The requirement that the Keweenawan poles be the consequence of the oscillation of the m/M ratio involves the assumption that normal and reversed poles lie on a great circle passing the sampling site<sup>7,14</sup>. As can be seen in Fig. 1a, this requirement is fulfilled for both arms within the limitations of accuracy of the available poles.

1 001 000

The second test involves palaeointensity data. The models shown in Fig. 2 predict the palaeointensity ratios of reversed and normal rocks at the Lake Superior area to be about 0.95 (case I) and 2.3 (case II), respectively. The observed averaged ratio of NRM intensities (Table 1) for six Keweenawan formations is  $1.24\pm1.02$  (s.d.), with a range 0.63-3.29 (ref. 7). On the other hand, the average absolute palaeointensity ratio of reversed and normal units (only three formations studied) is  $1.94\pm1.64$  (s.d.) with a range from 0.62 to 3.77 (refs 7, 20, 21). Thus the palaeointensity ratio varies so widely that we cannot define its average value well and we cannot, therefore, distinguish between case I, case II and the geocentric axial dipole case. More intensity studies with Thellier method, such as performed in the Thunder Bay district<sup>7</sup>, are needed in the Lake Superior area to develop the two-dipole models.

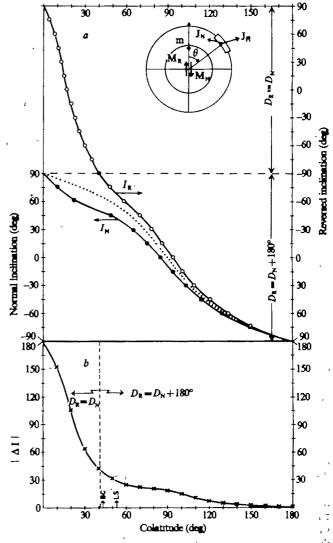

Fig. 3. a. The global values of inclinations due to the two-dipole model shown in the index figure (case I), as a function of colatitude  $\theta$ . Open (closed) symbol for reversed (normal) data. The arrows  $(I_{pe}, I_{pe})$  denote the average Keweenswan inclinations. Dotted curve is the axial geocentric dipole field inclination. b, The deviation  $|\Delta I|$  from 180° of reversals of inclinations calculated from the data shown in  $\alpha$ . The vertical broken line indicates the colatitude limit for which the declinations of normal and reversed remanences depart 180°. LS, colatitude of the Lake Superior area as measured from the true Middle/Lower Keweenswan pole (TKM in Fig. 1b), GC, corresponding colatitude of the Grand Canyon area.

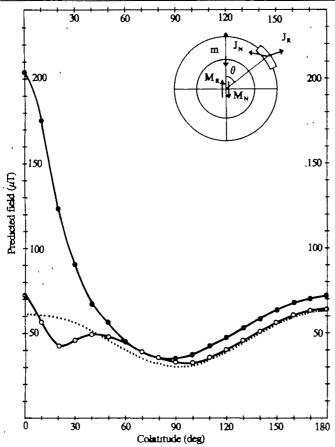

Fig. 4 The global values of field intensities due to the two-dipole model shown in index figure (case I), as a function of colatitude θ. Open (closed) symbol for reversed (normal) data. The curves are normalized so that at the palaeocolatitude 53° the intensity ratio of reversed and normal data is ~0.95 as produced by the case I model (see text) Dotted curve is the present Earth's magnetic dipole field intensity curve

The third test involves a global study of field reversals of late Precambrian age (1,200-1,000 Myr). Figures 3 and 4 show the inclination and intensity values as a function of colatitude for normal and reversed epochs predicted by the two-dipole model (case I). It can be seen (for example, Fig. 3b) that asymmetric reversals should be observed at all colatitudes, and thus the feature is not restricted to the Lake Superior region. Particularly, strong asymmetry in inclination should be observed at colatitudes  $\theta \le 60^\circ$ . Note, however, that when the colatitude is smaller than  $\sim 40^\circ$ , normal declination  $(D_N)$  becomes equal to the reversed one  $(D_R)$  (Fig. 3), and the term 'reversal' becomes confusing (see ref. 14). In case II the global asymmetries are much larger because the ratio of dipole moments is very large.

Unfortunately, the worldwide data of Keweenawan age interval reveal only few studies where both normal and reversed data are documented. These data are of poorer quality than from the Keweenawan. However, in all of these cases (for example, Barby lavas in Africa<sup>22</sup>, the Late Gardar dykes in Greenland<sup>16</sup>, the Jacobsville sandstone in Canada<sup>23</sup> and the Grenville/Sveconorwegian rocks in Canada<sup>18</sup> and Scandinavia<sup>7</sup>) the reversals are always asymmetric. The inclinational asymmetry in these studies is  $30^{\circ} \pm 18^{\circ}$  (s.d.) while the corresponding declinational asymmetry is 19°±7° (s.d.) on average. Of particular importance and in support for our two-dipole model, are palaeomagnetic data from Yenisei Ridge (1,200-900 Myr)<sup>24</sup>, where several successive reversals are found, all of which are asymmetric. Another test will become available should the reversals 25,26 in the Grand Canyon area prove to be asymmetric also, because the Grand Canyon sequence is contemporaneous with the Keweenawan one<sup>7,26</sup>. The colatitudinal difference between the Lake Superior and Grand Canyon areas (relative to true Keweenawan poles) is  $\sim 10^{\circ}$  and etherefore the asymmetry, if it exists in the Grand Canyon, should agree with the curves in Figs 3 and 4.

We conclude that the oscillating co-axial two-dipole model can describe the available palaeomagnetic data of the Lake Superior area and suggests in particular that the puzzling asymmetric reversals of Keweenawan age may reflect persistent zonal *Nd* geomagnetic field components between 1,200 and 1,000 Myr.

We thank Dr H. C. Halls for helpful discussions, Dr D. H. Watkinson for permission to quote unpublished data on the Coldwell Complex and Mrs Kirsti Blomster for drawing the figures.

## High-resolution seismic reflection profiles reveal fracture zones within a 'homogeneous' granite batholith

#### J. A. Mair\* & A. G. Green

Division of Seismology and Geothermal Studies, Earth Physics Branch, Energy, Mines and Resources Canada, Ottawa, Canada K1A 0Y3

Several countries are investigating the use of plutonic rock bodies for the ultimate disposal of radioactive waste material. Among criteria<sup>2,3</sup> that must be met before a rock body is mined for a repository is that it must have a low in situ permeability. As the permeability of most unfractured plutonic rocks is very low, the problem reduces to finding those bodies which do not contain major connected fractures that would allow radioactive material to be transported by water to the blosphere. We report here that a high-resolution seismic reflection survey across the central region of an Archaean granitic pluton, which on the basis of other data might be defined as relatively homogeneous, identifies major sub-horizontal fracture zones at depth. Such fracture zones, which could be a major hazard for the containment of radioactive wastes, may therefore be detected before selection of a repository site by a combination of high-resolution seismic reflection surveying and suitably located deep drilling.

The Lac du Bonnet batholith is a 96×25 km pluton trending ENE-WSW in southeastern Manitoba, close to the border with Ontario<sup>4</sup>. This pluton is one of the crystalline rock bodies being studied at four research areas in the southern Canadian Shield by Atomic Energy of Canada Limited. It contains the proposed site of Canada's Underground Research Laboratory for conducting heating and other in situ scientific experiments in the subsurface.

Geologically, the Lac du Bonnet batholith is situated within the southern portion of the English River gneissic belt, a major Archaean belt within the western Superior tectonic province of the Canadian Shield (ref. 5; fig. 1). The central and major

portion of the batholith has been described as a homogeneous single phase of medium- to coarse-grained granite<sup>4</sup>. Minor heterogeneity is observed in the form of xenoliths of the surrounding country rock and pegmatite and aplite dykes. Economically important mineralization (such as the Tanco deposit<sup>4</sup>) is restricted to pegmatites that intrude the country rock near the northeastern end of the batholith<sup>6</sup>.

Field evidence shows that the Lac du Bonnet batholith is intrusive into the adjacent formations and that the intrusion may have postdated the last phase of the Kenoran orogeny (~2,600 Myr) in this region<sup>6</sup>. This conclusion is supported by the fact that the batholith has undergone the least deformation of the rock units in the area<sup>4</sup>. In particular, there is only a small amount of deformation in the central region of the batholith, and this may be related to minor diapiric movement of the batholith after partial or complete crystallization.

The fractures and lineaments in the area of the batholith have been studied using satellite imagery, aerial photographs of two selected sites of 56 km<sup>2</sup> and ground observations at about 140 outcrops<sup>4</sup>. Although these studies showed three trends of fractures and lineaments (N-S, NE-SW and NW-SE), no major surface fractures were observed within the batholith. In a comparison with the lineament study by Brown and Thivierge<sup>7</sup> of 317 plutons larger than 3 km in Ontario, Tammemagi et al.<sup>4</sup> show a graph which we interpret as placing the Lac du Bonnet batholith in the top 3% of rock bodies in terms of structural integrity and percentage outcrop.

Several surface geophysical surveys have been conducted across the Lac du Bonnet batholith to delineate fractures and changes in lithology. A N-S gravity traverse across the batholith and neighbouring formations reveals the low-density batholith at the centre of a negative regional gravity anomaly. Towards the north end of the batholith, superimposed on the negative regional anomaly, is a shorter-wavelength positive anomaly that has been interpreted as due to a high-density body situated at a depth >4 km. Various density models that fit these data indicate a relatively constant density distribution within the batholith above a depth of ~4 km.

Electromagnetic and resistivity surveys 10-12 across the central portion of the batholith have failed to produce any structural

information, due to a widespread overburden layer of highly conductive clay, 0-25 m thick. Some evidence for lateral heterogeneities was obtained from a combined low-level (150-m flight altitude) magnetic total field and gradiometer survey<sup>13</sup>. The total field data show the magnetic field increasing smoothly from the boundaries of the batholith towards its centre. Near the centre, in the vicinity of the gravity high, are two particularly high-amplitude anomalies that have yet to be explained. The magnetic gradiometer survey revealed numerous anomalies across most of the batholith<sup>13</sup>, but due to the lack of outcrop it has not been possible to test either the significance of these anomalies or relate them to specific lithological or structural changes within the batholith.

In 1979 and 1980, five high-resolution MINI-SOSIE [trademark of Société Nationale Elf-Aquitaine (Production)] seismic reflection profiles were recorded within a 2.2 × 2.2 km area of the south-central region of the Lac du Bonnet batholith (Fig. 1). The principal advantage of MINI-SOSIE over conventional seismic reflection systems is its inexpensive non-destructive energy source, consisting of one or more small Earth tampers<sup>14,15</sup>. In the field, 24 receiver arrays of nine 40-Hz geophones spread over 10 or 20 m were deployed at 10 or 20 m intervals. The seismic source provided a random series of pulses to the Earth and about 3,000 pulses, suitably time shifted and added, were recorded every 10 or 20 m to provide 12-fold common reflection point coverage. A split spread configuration was adopted and a digital rate of 500 samples per s was used for each 1 s seismic record.

Conventional seismic processing techniques (static and dynamic corrections, bandpass filtering, prestack sliding gain and common reflection point stacking) have been applied to give the two E–W seismic sections shown in Figs 2 (line 1) and 3 (line 3). The line 1 section has also been passed through a wide-band velocity filter (four input traces per output trace; passband -1.7 to  $+1.7 \, \mathrm{km \, s^{-1}}$ ) to remove prominent low apparent velocity arrivals associated with the overburden layer.

Figures 2 and 3 show that the Lac du Bonnet batholith is not as homogeneous in its central region as suggested by most other studies, but contains fractures and possible intrusions. There are at least two major sub-horizontal (dips < 25°) reflection

Fig. 2 Twelve-fold common reflection point seismic section collected along line 1 (Fig. 1). Lettered reflection zones are discussed in the text. The positions of the cross lines and exploratory drill holes are shown at the top of the section. Receiver spacing 10 m. Depths shown are only approximate due to the lack of detailed seismic velocity estimates throughout the region.

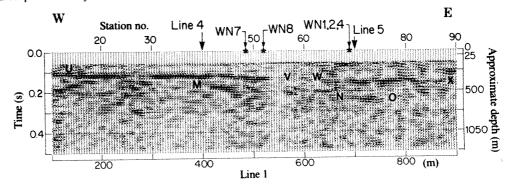

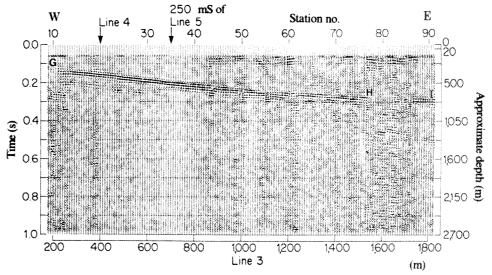

Fig. 3 Twelve-fold common reflection point seismic section collected along line 3 (Fig. 1). The position of the cross lines are shown at the top of the section. Receiver spacing was 20 m. Depths shown are only approximate due to the lack of detailed seismic velocity estimates throughout this region.

systems; UVWX in Fig. 2 and GH in Fig. 3. The true attitudes of these and other reflecting horizons are controlled by good-quality reflections on the cross-lines 1, 4 and 5 (Fig. 1).

The spectacular reflection zone GH (and possibly to I) on line 3 (Fig. 3) dips smoothly at an angle of 17° to the east and can be traced for a distance of 1.2 and possibly 1.6 km. On the N-S cross-lines this feature, which is represented by a series of strong reflections, has a more rugged character with a northward component of dip varying from 3 to 15°. It can be traced continuously from line 3 to line 1, where it is represented by the reflections MNO (Fig. 2). In the vicinity of line 1 this feature disappears and is replaced by the reflection system UVWX, which has apparent easterly and northerly dips of 8° and 9° respectively and can be mapped over the entire length of line 1 (Fig. 2).

Inclined drill holes near the cross-over of lines 1 and 5 (Fig. 1) have intersected major fracture zones starting at depths projected updip of ~360 and 600 m (ref. 16) which account for the reflections UVWX and MNO respectively in Fig. 2. The fractures near 360 m depth have been studied extensively by (1) standard geophysical logging techniques, (2) core logging (geological, geochemical and geophysical), (3) television logging<sup>16</sup>, (4) hydraulic conductivity methods<sup>17</sup> and (5) tube wave analyses<sup>18,19</sup>. The television log confirms that they dip at shallow angles in a northeasterly direction, and the hydraulic conductivity and tube wave studies show that some fractures have high permeabilities. Preliminary analysis of data from hole WN7 shows that it has intersected the fracture zone UVWX at a depth of ~300 m, in excellent agreement with the depth predicted

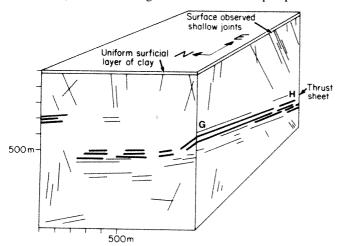

Fig. 4 Hypothetical block section of the Lac du Bonnet batholith viewed from the intersection of lines 3 and 4 (Fig. 1). A uniform (20 m thick) surficial layer of clay covers the batholith in this region. The sketch emphasizes the main features of the postulated thrust sheet G-H of Fig. 3.

from the seismic data. Note that the drilling of WN7 near this depth disturbed the water level in holes WN1 and WN4 (C. C. Davison, personal communication).

We interpret the two reflection systems as originating from a pair of en echelon fault zones with a regional dip of 12° (UVWX)-18° (GH) along an ENE-WSW to NE-SW azimuth. Locally, the attitudes of the faults vary due to relief along the strike directions (Fig. 4). The projected surface outcrops of the fault zones lie beneath the Winnipeg River, and may have influenced the drainage pattern in this region. We suggest the original fractures developed with some relief along strike and movement was along the smooth shear planes (UVWX and GH in Figs 2 and 3 respectively) parallel to the dip direction.

The low dip angles of the fault zones are probably indicative of thrust faulting, caused by horizontal compressional stress in an ENE-WSW to NE-SW direction, approximately parallel to the long axis of the batholith. This stress field was not prevalent in Archaean times, during the batholith's intrusion<sup>5</sup>, when the largely N-S compression of the regional stress field resulted in the E-W trending tectonic belts of the western Superior province (Fig. 1). However, the postulated ENE-WSW to NE-SW compressional stress field is parallel or sub-parallel to the current regional stress field inferred for much of northern North America. Focal mechanism studies of earthquakes in eastern Canada and the eastern United States show E-W to NE-SW deviatoric compressional and near-vertical deviatoric extensional axes<sup>20,21</sup>, and this same stress field has been determined by hydro-fracture measurements<sup>22</sup> and with greater variability by in situ stress measurements at Red Lake, 120 km north-east of the Lac du Bonnet batholith, show predominant NE-SW deviatoric compression<sup>24,25</sup>. A similar NE-SW stress field has been suggested for sediments beneath the western Prairies of Canada, based on the preferred orientation of spalling in oil wells and the results of hydraulic and steam fracturing<sup>26</sup>. Although the E-W to NE-SW stress field may be a feature of much of the northern North American continent, the source of the stress may not be the same for the different regions.

This study of the Lac du Bonnet batholith, a rock body which on the basis of other data may be classified as relatively homogeneous, shows it to contain numerous fractures, some of which are interconnected and may reach to the surface. A hypothetical block section that might be viewed from the junction of lines 3 and 4 in Fig. 1 is sketched in Fig. 4. The high permeability and size of some of these fracture zones (UVWX is >50m thick and affects an area of at least  $400\times800$  m) demonstrate that they may be a major problem in the search for a suitable repository site.

Our results indicate the feasibility of subjecting any potential repository site to a comprehensive high-resolution seismic reflection survey. A three-dimensional seismic reflection survey, combined with an appropriate exploratory drilling programme,

could delineate blocks of a rock body that may be relatively unfractured and thus suitable for a nuclear waste repository.

We thank M. Berry, M. Dence, D. Forsyth, H. Hasegawa, C. Wright and various employees of Atomic Energy of Canada Limited for critical reviews of the first draft of the manuscript. Atomic Energy of Canada Limited provided the funds for the seismic survey. Earth Physics Branch publication number 958.

## **Bacterial origin of East Australian** continental margin phosphorites

G. W. O'Brien\*, J. R. Harris†, A. R. Milnes† & H. H. Veeh\*

\* School of Earth Sciences, The Flinders University of South Australia, Bedford Park, South Australia 5042, Australia † CSIRO Division of Soils, Private Bag No. 2, Glen Osmond, South Australia 5064, Australia

Many models of the origin of marine phosphorites require a sediment rich in organic matter, which by decomposition releases phosphorus for the precipitation of carbonate fluorapatite1-7. This concept is useful in explaining contemporary phosphorite in areas of very high productivity off the coasts of Peru-Chile and South West Africa 8-10 where there are high organic matter fluxes to the sea floor<sup>4-7,11</sup>. It does not explain the origin of marine phosphorite deposits which formed in regions of limited oceanic upwelling and productivity 12-1 The East Australian continental margin, an area of phosphomodern analogue of an 'East Coast' phosphogenic province 15-17 with low productivity over the uncertainty genesis throughout the late Pleistocene and Holocene 13,14 with low productivity over the upper slope region where the most recent phosphorites have been found<sup>18</sup>. Evidence is reported here for the carbonate fluorapatite in the East Australian phosphorites being located within bacterial cellular structures, and a model proposed for the origin of these deposits through the slow bacterial assimilation of phosphorus from seawater in an area of restricted sedimentation.

Phosphatic nodules and sediments were recovered by dredging and piston and box coring on the East Australian continental shelf and upper slope between 29° and 31° S at depths ranging from 210 to 450 m. In box cores, late Pleistocene to Holocene phosphatic nodules occur within unconsolidated sediments of silt to sand-sized quartz, glauconite pellets and planktonic foraminiferal tests. The sediments have a grain-supported fabric: the low concentration of fines is believed to have resulted from winnowing processes. Nodules of Holocene age (from uranium-series data) always occur within a few centimetres of the sediment surface. Nodules having uranium-series ages in excess of 240,000 yr often occur within the top 10 cm of the cores. This is consistent with a low sedimentation rate, or with significant mechanical reworking and erosion. Based on the uranium-series dating of three phosphatic nodules occurring at different depths in piston core P904 (Table 1), we interpret the distribution of nodules in the uppermost parts of the cores to be the result of a low sedimentation rate in the region. Assuming that the nodules formed at or near the sediment-water interface, the uranium-series ages indicate an average sedimentation rate of <1 cm kyr<sup>-1</sup>. Table 2 summarizes geochemical data from six samples of nodules and sediments. The organic carbon concentrations are low compared with values reported for high productivity phosphogenic provinces. The phosphorus values for the sediments are also low. This suggests that carbon and phosphorus fluxes to the East Australian sediments are several orders of magnitude lower than those obtained from Peru-Chile and South West Africa<sup>4,5,11</sup>

Examination of freshly fractured surfaces of late Pleistocene to Holocene phosphatic nodules by scanning electron microscopy (SEM) with energy dispersive analysis revealed that the detectable phosphorus is located in structures morphologically resembling bacteria. The cellular structures are composed of apatite and resemble non-filamentous, botuliform bacilli 1.5-2.0 µm in length (occasionally as short as 1.0 µm) and 0.75-1.0 µm in width, generally cylindrical, but commonly with a tendency to be ovoid to subturbinate, with one end tapering to become more pointed than the other (Fig. 1a).

Together with fine clay minerals, the bacilli are concentrated in the matrix of the nodules, and occur attached to all solid surfaces including quartz grains, glauconite pellets and foraminiferal tests. Attachment of the cells to a surface is generally by the narrow end of the cell, but there is no development of a stalk. The morphology of the bacteria is seen most clearly on shell fragments where their numbers are small (Fig. 1b, c). There the bacilli did not form chains or mass into colonies, but appear to be randomly distributed, as if a motile cell had migrated to an anchorage. Where aggregations became greater, contiguous colonial growth occurs (Fig. 2a), and in some instances, dense bacterial colonies are layered with the long axes of the cells parallel to one another but normal to the supporting surface (Fig. 2b).

In contrast to the phosphatic nodules, the associated sediments are almost free of bacterial structures. Pyrite framboids are present in both the late Pleistocene to Holocene nodules and in the sediments in association with carbonaceous material; but they are not abundant, and where present usually occur within foraminiferal tests. Middle Miocene ferruginous phosphatic nodules from the same region contain few bacilli: the apatite is mostly present as well-developed crystals (Fig. 2c). In both the late Pleistocene to Holocene and middle Miocene nodules, sharp, well-defined X-ray diffraction peaks indicate good apatite crystallinity.

Given that all of the carbonate fluorapatite in the younger East Australian phosphatic nodules is present within bacterial structures, what evidence is available to help define the environmental conditions suitable for their proliferation, and identify their type? A consistent morphological feature shown in our micrographs is the relatively uniform size and shape of the bacilli, both within and between sampled sites. This suggests that we may be dealing with one specific organism, rather than with the range of forms that would signify a mixed population.

The absence of a mixed bacterial population indicates that the ecological niche occupied by this organism was highly restrictive, and possibly unique to a single species or group of closely related and morphologically indistinguishable species. The high degree of preservation of whole bacterial cells in the nodules suggests that they have been free from competition, predation and grazing. The most likely synopsis of these ecological condi-

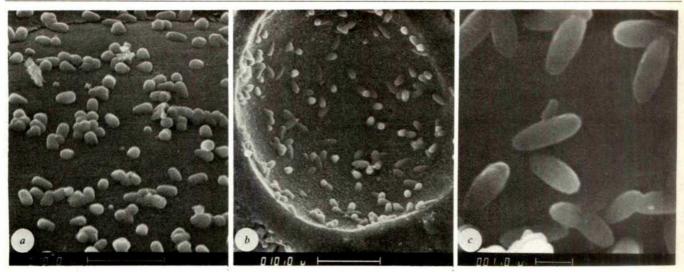

Fig. 1 a, Bacterial cells replaced by apatite encrusting a foraminiferal shell surface. Amongst the many sausage-shaped bacilli are some that are turbinate and taper towards one end. Early Pleistocene phosphorite nodule P895(120cm) – 1. Scale bar, 10μm. b, The scatter of bacterial cells in this foraminifer suggests that the bacilli may have been motile and migrated to this protected site before anchoring by the narrow end. Early Pleistocene phosphorite nodule P884(78cm) – 1. Scale bar, 10μm. c, The characteristic bacillary shape, now replaced by apatite, illustrates the typical morphology of the bacteria found in the East Australian phosphorite nodules. Holocene phosphorite nodule P883(20cm) – 1. The bacteria occur on a shell surface. Scale bar, 1μm.

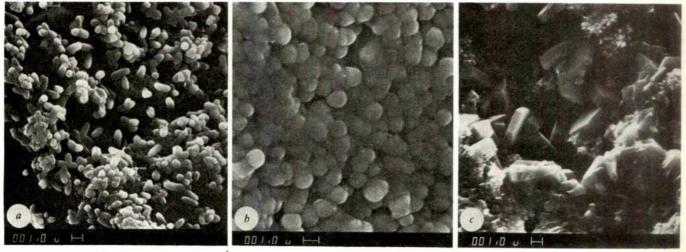

Fig. 2 a, In sites where bacterial growth became intensive enough to form colonies, the uniformity of cell shape and the state of their preservation are outstanding features. Holocene phosphorite nodule P883(20cm) – 1. Bacteria are clustered on detrital silicate grain. Scale bar, 1μm. b, In tightly-packed colonial growth the bacterial cells are polarized with long axes normal to the supporting surface, but apatite replacement still reveals confinement within cellular structures. Early Pleistocene phosphorite nodule P895(120cm) – 1. Scale bar, 1μm. c, Well crystallized apatite filling fracture within middle Miocene phosphorite nodule G18. Scale bar, 1μm.

tions suggests a biological desert in which few organisms grow, in which the growth rate of the individual cells may be quite slow, and in which a slow sedimentation rate provides minimal energy and/or nutrient inputs.

While there are limited criteria on which to base the identification of the bacteria, there are some morphological features which preclude membership of several taxonomic groups commonly implicated in phosphate transformations. On this basis, the sheathed bacteria which metabolize iron, the budding bacteria which metabolize manganese, and the stalked bacteria such as the caulobacters<sup>19,20</sup>, which grow in very dilute media, are excluded. Similarly they are not slimy filamentous actinomycetes such as *Bacterionema matruchotii* or *Leptotrichia buccalis* which are found in the oral cavities of man and primates<sup>21,22</sup>, and which deposit apatite in dental calculus and plaque deposits. The cells are not curved in the manner of spirillums or vibrios; nor flexuous, sinusoidal, nor coccal. None of the micrographs display swellings implying Gram-positive sporing rods, or the cluster formations of the corynebacteria<sup>23</sup>.

About 90% of the bacteria isolated from marine environments are Gram-negative rods; usually pseudomonads predominate<sup>24,25</sup>. Many of these bacteria are not specific to marine

environments, but can occur in fresh waters and soils<sup>26</sup>. The bacteria that we have observed are probably Gram-negative aerobic pseudomonads or facultatively anaerobic enterobacteria. The most attractive hypothesis is that they are facultatively chemolithotrophic pseudomonads with the ability to utilize hydrogen or carbon dioxide. This would have enabled them to inhabit the restricted ecological niche with very low energy input which the East Australian upper continental slope provided during phosphogenesis. A parallel group of halophobic pseudomonads inhabit reticulated distilled water storage systems where both nutrient and energy supply are drastically limiting<sup>19</sup>.

The phosphorus contents of microorganisms are usually high, of the order of 5-10% of the organic fraction<sup>27</sup>. Where an organism grows very slowly and is efficient in extracting phosphorus from the low concentrations commonly present in seawater, it may accumulate normal or even elevated concentrations of nucleic acids, phospholipids and polyphosphate. The apatite forming the cell outline is not an encapsulation, but rather an intracellular deposit. It is not likely to have precipitated internally in vivo, but is more likely a post mortem transformation of assimilated phosphorus. This presupposes either that the bacteria retained cellular organization for an

nodule

appreciable period after active metabolism ceased without degeneration by lysis and without leaching losses of soluble polyphosphates, or that precipitation of apatite occurred rapidly.

There is no evidence to support a hypothesis that the growth of the organism we have identified in the East Australian phosphorites needed episodic accessions of readily decomposible organic detritus. In particular, there is a lack of appreciable sulphides, an absence of fish bones in the sediments, uniformity of the bacterial population, and very low organic carbon concentrations in both the sediments and the phosphatic nodules.

While limited seasonal upwellings (and associated higher nutrient levels) are known to occur sporadically on the East Australian continental shelf<sup>28,29</sup>, these usually occur within 15 km of the coast and are unrelated to the phosphogenic region, which is some 35-40 km offshore.

We conclude that the late Pleistocene to Holocene phosphatic nodules on the East Australian continental margin have been formed by the accumulation of carbonate fluorapatite during the post mortem alteration of phosphorus-rich bacterial cells. Assimilation of high phosphorus levels from seawater of average phosphorus concentration would occur slowly in a slow-growing bacterial population. For this reason a very low sedimentation rate is critical, otherwise the bacterial growth would be swamped by sediment. We envisage the microbial growth gradually cementing the unconsolidated sediments30, although fine clay minerals in the phosphatic sediment must also be important in the lithification process. The cemented phosphatic layer is later broken into nodules, either by the action of endolithic organisms or by the effect of strong bottom currents, or probably both. The presence of fine clay within the bacteriarich matrix suggests that bottom current velocities during times of phosphogenesis were substantially lower than present day current velocities<sup>31,32</sup> that are sufficiently high to winnow fines from the sediment. We are not certain of the environmental factors which controlled the onset and termination of bacterial growth and phosphogenesis, although they may have been related to a subtle balance between erosion and deposition which was controlled by variations of the East Australian current.

Carbonate fluorapatite in the middle Miocene nodules occurs largely as well-developed crystals. These may have formed during diagenesis (Fig. 2c) of phosphate present initially in bacterial structures. Some similarities of depositional environment of the East Australian phosphorites to other more ancient deposits of the 'East Coast' type may suggest that some of these older phosphorites also had a bacterial origin, but that this has been obscured by subsequent diagenetic processes. Structures composed of apatite and similar to those we have described also occur in phosphorites off Peru-Chile and South West Africa<sup>6,33</sup> If they prove to be bacterial, our model for phosphorite formation may represent a general phenomenon.

# Atmospheric concentration of ammonia in Massachusetts and deposition on vegetation

#### John D. Tjepkema & Robert J. Cartica

Harvard Forest, Harvard University, Petersham, Massachusetts 01366, USA

#### Harold F. Hemond

Department of Civil Engineering, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

Ammonia has an important role in atmospheric chemistry and the soil nitrogen cycle, and it has long been suggested that terrestrial ecosystems may be important sources and sinks for atmospheric ammonia in both gaseous and particulate form<sup>1</sup> But there is relatively little information on the average atmospheric concentrations of NH<sub>3</sub> gas and particulate NH<sub>4</sub> and their fluxes to and from ecosystems. Furthermore, much existing data are unreliable because of difficulties in separating gaseous NH<sub>3</sub> from particulate NH<sub>4</sub> (refs 1, 5). We have used a new method<sup>5,6</sup> which overcomes these difficulties and have made continuous measurements for a 1-yr period at a rural location in Massachusetts. From these data and from measurements of the rate of deposition of ammonium on plastic and natural leaves, we conclude that particulate NH<sub>4</sub> can be a significant nitrogen source for ecosystems, especially pine forests. In contrast, gaseous NH3 is probably of little importance as its concentration is very low.

In our measurements (Fig. 1) we found a strong seasonal pattern in the atmospheric concentrations of NH<sub>3</sub> and NH<sub>4</sub>, with maximum values during the summer months. This suggests that much of the NH3 may come from agricultural or natural sources, rather than from the combustion of oil and coal. The measured concentrations of particulate NH<sub>4</sub> are similar to those reported elsewhere in the United States but the values for gaseous NH<sub>3</sub> are lower than most other reports<sup>1,3</sup>. The reasons for this are unknown but may be partly due to methodology. Most measurements of NH<sub>3</sub> have removed NH<sub>4</sub> particulates by placing a filter upstream of the NH<sub>3</sub> collector. Reactions on the filter may release NH<sub>3</sub>, causing an overestimate of NH<sub>3</sub> concentration<sup>1,5</sup>. It is unlikely that the alternative methodology that we used underestimated gaseous NH<sub>3</sub>, as placing collection tubes in series demonstrated a collection efficiency of at least 90%, which is consistent with theoretical prediction<sup>5,6</sup>. Another factor may be the high concentrations of acidic aerosols in the eastern United States. Calculations based on NH<sub>4</sub> and H<sup>+</sup> concentrations in precipitation predict7 very low concentrations of atmospheric NH<sub>3</sub>. Finally, there may be few major sources of atmospheric ammonia in the region, due to the acidity of the soil and low density of farms. Using similar methods, low concentrations (0.2 µg m<sup>-3</sup>) of gaseous NH<sub>3</sub> have also been measured in Sweden<sup>5</sup>, but higher values (3 µg m<sup>-3</sup>) in the Netherlands<sup>6</sup>.

Farquhar et al.<sup>2</sup> have determined the NH<sub>3</sub> compensation point, at which leaves neither gain nor lose NH<sub>3</sub>, for several plant species. Extrapolation of their data to our mean summer temperature of 20 °C suggests a NH<sub>3</sub> compensation point of 1  $\mu$ g m<sup>-3</sup>, which is much higher than our mid-summer NH<sub>3</sub> concentration of 0.2  $\mu$ g m<sup>-3</sup>. This suggests that Massachusetts ecosystems might actually lose NH<sub>3</sub> to the atmosphere. Even if NH<sub>3</sub> uptake is possible at these low concentrations, measurements of uptake at higher concentrations suggest a deposition velocity of ~1 cm s<sup>-1</sup> (ref. 2). Assuming leaves to be present from 1 June to 1 October, this deposition velocity results in an estimated NH<sub>3</sub> uptake equivalent to 0.13 kg N ha<sup>-1</sup>, which is negligible compared with the nitrogen input in precipitation.

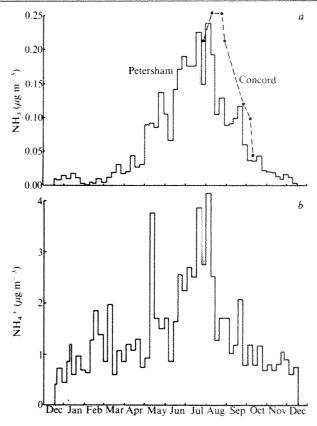

Fig. 1 Atmospheric concentrations of NH<sub>3</sub> (a) and NH<sub>4</sub><sup>+</sup> (b) measured during 1980 in a forest clearing at Petersham in central Massachusetts. Gaseous NH3 was collected in glass tubing coated for 45 cm with 5% oxalic acid as described by Ferm<sup>5</sup>. The intake was at 1.5 m height and air was drawn through the tubing at a flow rate of 2.71 min<sup>-1</sup>, using a vacuum pump and critical orifice to , using a vacuum pump and critical orifice to control flow rate. Collections were made over 7 days with particulate NH<sub>4</sub> being collected at the downstream end of the tubing on a 0.4 μm, 47 mm, Nucleopore filter. Analysis of NH<sub>3</sub> was by electrode (Orion 95-10). The means of two collectors are plotted; the average difference from the mean of the individual values was 8.6% for NH<sub>3</sub> and 3.2% for NH<sub>4</sub>. Also shown are values for NH<sub>3</sub> concentration (mean of two collectors) measured over 24-h periods during late summer 1980 at Thoreau's Bog, Concord, near Boston; the intake height was 0.8 m and analysis of NH3 was by the phenol-hypochlorite method.

Unlike gaseous NH<sub>3</sub>, particulate NH<sub>4</sub> may be a significant nitrogen source for forests in Massachusetts. However, available data do not allow an accurate estimate of the rate of deposition of particulate NH<sub>4</sub> to forests, so we made experimental determinations. A correlation coefficient of 0.67 was found between the NH<sub>4</sub> collected on rectangular plastic leaves and the concentration of particulate NH<sub>4</sub> in the atmosphere (Fig. 2). Other factors such as wind speed and particle size may also have influenced the rate of deposition, and there may have been some exchange of gaseous NH3 between the atmosphere and the deposited aerosols. In the above experiments leaves were exposed at a height of 11 m in a clearing, but in other experiments (to be described elsewhere) there was no difference in NH<sub>4</sub> deposition on leaves placed in the canopy at two different forested sites. Likewise, there was no difference in NH4 deposition on a surface area basis between natural leaves of Kalmia latifolia and Pinus strobus and plastic leaves simulating broad leaves and pine needles. Unexposed leaves were used as blanks to control for NH<sub>4</sub> arising from internal leaching. However, the rate of NH<sub>4</sub> deposition per unit of surface area was 2.0 times greater (r = 0.93, P < 0.01) for plastic leaves that simulated Pinus strobus needles than for rectangular plastic leaves.

Our measurements of the atmospheric concentration of particulate NH<sub>4</sub> and its rate of deposition on plastic and natural leaves can be combined to estimate the annual nitrogen input to

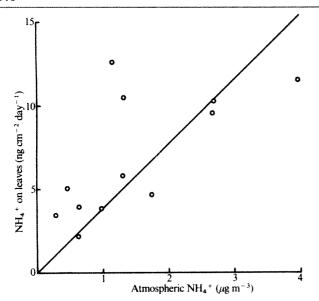

Fig. 2 Deposition of NH<sub>4</sub> on plastic leaves as a function of atmospheric concentration of particulate NH<sub>4</sub><sup>+</sup>. The leaves were 10 rectangles of polyethylene  $(0.1 \times 2.0 \times 5.8 \text{ cm})$  that were exposed at a height of 11 m for 24 or 48 h. Ammonium was leached from the leaves by immersing each one in a vial containing 20 ml of deionized water for at least 1 min with agitation. Ammonium was measured by electrode, with a correction for unexposed blank leaves. Each point is the mean of the 10 individual determinations; the standard error averaged 12% of the mean. A linear regression through the origin is plotted: r = 0.67, P < 0.02

forests from this source. Assuming a leaf area (both sides) of 8 m<sup>2</sup> per m<sup>2</sup> of ground surface and using the regression line in Fig. 2 we calculated a deposition velocity of  $0.35 \text{ cm s}^{-1}$  for broad-leaved trees. The calculated deposition velocity for pines was 0.72 cm s<sup>-1</sup> because deposition of NH<sub>4</sub> per unit of surface area was 2.0 times greater (see above). For deciduous, broadleaved forests the leaves were assumed to be in place from 1 June to 1 October, during which time the average particulate NH<sub>4</sub><sup>+</sup> concentration was 2.1 μg m<sup>-3</sup>. For this period the calculated deposition of NH<sub>4</sub><sup>+</sup> was 0.6 kg N ha<sup>-1</sup>. For pine forests the leaves were present all year and the average concentration of  $NH_4^+$  was 1.4  $\mu g m^{-3}$ . From this we calculate a  $NH_4^+$  deposition of 2.5  $kg N ha^{-1} yr^{-1}$ .

The above estimates suggest that dry deposition of particulate NH<sub>4</sub> on leaf surfaces may be a significant sink for atmospheric ammonia and a source of nitrogen for forests, especially pine forests. There is little nitrogen fixation in Massachusetts forests8, so the only known nitrogen input is from precipitation which totals  $6.5 \text{ kg N ha}^{-1} \text{ yr}^{-1} \text{ as NH}_4^+ \text{ plus NO}_3^- \text{ at a location } 160 \text{ km}$  to the north. Thus dry deposition of particulate NH $_4^+$  appears to be a significant source of nitrogen relative to precipitation, while dry deposition of gaseous NH3 is not. This supports previous evidence that dry deposition of other components of aerosols such as acids, nitrates and sulphates is important<sup>10-14</sup>. Further studies are needed to quantify these inputs more precisely, but it seems likely that dry deposition of aerosols containing ammonium and nitrate is an important factor in maintaining the productivity of pine and other forests. This may be especially true for forests on poor soils of low nitrogen content.

## A sterile defender morph in a polyembryonic hymenopterous parasite

Y. P. Cruz

Division of Biological Control, Department of Entomological Sciences, University of California, Berkeley, California 94720, USA

Early in the development of polyembryonic Encyrtidae, a number of larvae are formed that are morphologically different from their later sibs. These larvae die without pupating. They have been described as asexual<sup>1</sup>, teratoid<sup>2,3</sup> or precocious<sup>3</sup>, and it has been suggested that they render the host suitable as food and habitation for the later, normal larvae1.4. I now report findings which demonstrate that the precocious larvae constitute a defender morph, eliminating other internal parasites that would otherwise compete with, and potentially preclude the development of, their normal sibs.

A colony of an as yet undescribed species of the encrytid genus Pentalitomastix has been maintained in the laboratory on its natural host, the phycitid moth Anagasta kuehniella (Zeller). Female wasps oviposit in the host egg but the resulting parasitized host larva does not succumb until after it spins a cocoon some 6 weeks later. Instead of pupating, the host larva 'mummifies', becoming no more than a sac filled with 100-200 parasite pupae. Sequential dissections of 250 parasitized hosts reveal that as in other polyembryonic encyrtids 1,2,5, the parasite egg develops into a mass of apparently undifferentiated cells, the polygerm, which gives rise to the numerous larvae that fill up the host 'mummy'. The first one or two parasitic larvae are invariably precocious (Fig. 1) and are found in the host larva within 10 days after deposition of the parasite egg. Precocious larvae continue to appear as the polygerm increases in size (24 have been found in one host) until the stage,  $4\frac{1}{2}$  weeks after egg deposition, when the polygerm dissociates into normal larvae. By the sixth week, the normal larvae are mature (Fig. 2) and only dead precocious larvae are recovered from dissected hosts.

Two solitary endoparasitic wasps, the braconid egg-larval parasite Phanerotoma flavitestacea Fischer, and the ichneumonid larval parasite Trathala sp., have also been maintained in the laboratory with Anagasta kuehniella as a factitious host. These parasites were originally reared from the phycitid Ectomyelois ceratoniae (Zeller). Dissections of 33 multiply parasitized A. kuehniella larvae exposed as eggs to P. flavites-

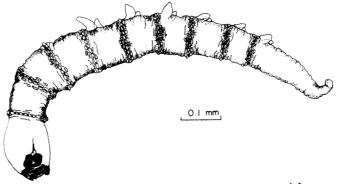

Fig. 1 Precocious larva of Pentalitomastix sp. recovered from 14-day-old A. kuehniella larva. The number of paired dorsal papillae is variable.

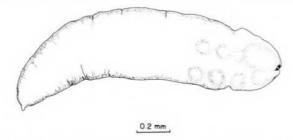

Fig. 2 One of 164 mature normal larvae of Pentalitomastix sp. recovered from 40-day-old A. kuehniella larva. Imaginal discs are apparent on the anterior third of the body.

tacea for 24 h and then to Pentalitomastix sp. for another 24 h each yielded one or more live precocious larvae and one wounded and dead P. flavitestacea larva. In 70% of these cases, the latter parasite was partially or entirely encapsulated (Fig. 3), indicating that an immune response, a common defense reaction in insects6, had been elicited in the host larva. For the reversed sequence of parasite exposure, 64% of 50 multiply parasitized hosts yielded wounded, dead and encapsulated P. flavitestacea larvae.

In contrast, no wounded or encapsulated parasite larvae were found in 250 A. kuehniella larvae exposed as eggs to P. flavitestacea alone. In each of 14 observed cases of superparasitism, encounters among P. flavitestacea larvae occurred within 1 or 2 days of hatching of the larvae, at which time the host larva was still within its chorion. These encounters were fatal to all but one parasite larva and the losers were dismembered, not merely wounded. When 65 multiply parasitized host larvae were dissected before formation of the precocious larvae, the P. flavitestacea larvae were found alive. These observations, together with the extreme motility and heavily sclerotized buccal structures of the precocious larvae, indicate that they attack and kill P. flavitestacea larvae. This could explain why in laboratory tests, Ectomyelois ceratoniae (Zeller) multiply parasitized by P. flavitestacea Fischer and Pentalitomastix plethoricus Caltagirone reportedly gave rise to the latter parasite alone7

A. kuehniella larvae multiply parasitized by Pentalitomastix sp. and Trathala sp. yielded wounded, dead and encapsulated larvae of the latter and one or more precocious larvae of the former. Despite the similarity in appearance and motility of these larvae, the precocious larvae 'won' in all 29 cases (Fig. 4). In each of six cases of superparasitism by Trathala sp., all parasite larvae but one were found wounded, dead and encapsulated. In nine hosts superparasitized by Trathala sp. and additionally parasitized by Pentalitomastix sp., no Trathala sp. larvae survived when precocious larvae were present.

The presence of castes and intergenerational cooperation characterizes eusocial insects8. Although the polyembryonic

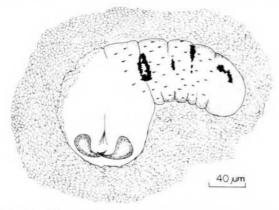

Fig. 3 Partially opened capsule containing dead, wounded, firstinstar Phanerotoma flavitestacea larva. Wounds appear as melanized lesions on the integument. The capsule consists of layers of cells that seem to have been laid down concentrically around the dead larva.

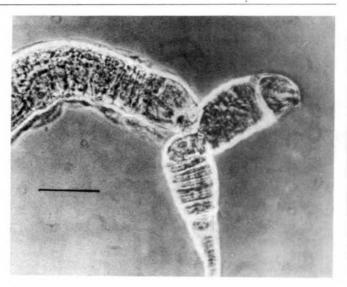

Fig. 4 Precocious larva of Pentalitomastix sp. (left) attacking larva of Trathala sp. Specimen was recovered from 49-day-old A. kuehniella larva exposed as an egg to Pentalitomastix sp. and as a 21-day-old larva to *Trathala* sp. Polaroid photograph of fresh specimen in Ringer's saline viewed through Tiyoda phase-contrast microscope. Scale bar, 0.2 mm.

Encyrtidae are not eusocial, the developmental pattern of known species involves the obligatory coexistence of a large number of individuals in a host vulnerable to attack by other internal parasites. Furthermore, any brood of parasites arising by polyembryony exists as a physically defenseless polygerm for an extended period during its own life and that of the host. Therefore, I suggest that the precocious larva serves as a defender morph and provides a means of increasing the competitive advantage and probability of survival of polyembryonic encyr-

## The path of axons in *Drosophila* wings in relation to compartment boundaries

John Palka, Margrit Schubiger & H. Stephen Hart

Department of Zoology, University of Washington, Seattle, Washington 98195, USA

We have tested the hypothesis that the paths taken by sensory axons in the peripheral nervous system of Drosophila are influenced by the boundaries between developmental compartments<sup>1</sup>. It has been proposed that differences in cell affinity keep the epidermal cells of adjacent compartments from intermingling2. Such differences in cell affinity might well also prevent the axons of sensory neurones, which are derived from the same populations as epidermal cells and which use them as growth substrates, from crossing compartment boundaries. However, as we report here, we have found that sensory axons in the wing of Drosophila do cross the boundary between the anterior and posterior compartments of the wing.

The thoracic segments of Drosophila melanogaster are each divided at least into anterior and posterior (A and P) compart-

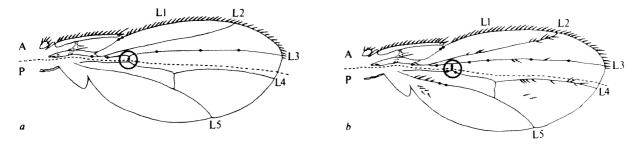

Fig. 1 Morphology of the wing of *D. melanogaster. a*, Wild type, with receptors on specific veins; *b, Hairy wing (Hw)*, with supernumerary receptors in many locations. L1-L5, longitudinal veins 1 to 5; •, large campaniform sensilla; :::, small campaniform sensilla on the radial vein; ---, A-P compartment boundary; heavy circle surrounds the area of the anterior cross vein (ACV), shown enlarged in Fig. 2. The compartment boundary in *Hw* animals was determined from the behaviour of mitotic recombination clones marked with *y* and *mwh* in the progeny of two crosses: y/y;  $mwh/mwh \times y Hw/Y$ ;  $Dp sc^{14}M(3)i^{55}/mwh^+$  and y Hw/FM6;  $mwh/mwh \times y Hw/Y$ ;  $Dp sc^{14}M(3)i^{55}/mwh^+$ . Egg collections were made over a 24-h period, and larvae aged 24-48 h were irradiated with a dose of 1,000 R (for further details, see ref. 6). Clones in flies homo-, hetero- and hemizygous for Hw were analysed and all behaved like similar clones in wild-type animals<sup>5</sup>. (For explanation of symbols and description of mutants, see ref. 16.)

ments. The presence of compartments is recognized because genetically marked clones of cells induced after a certain time in development never cross particular lines on the body surface. On the wing, the A-P boundary runs a few cells anterior to the fourth longitudinal vein<sup>1</sup> (L4; Fig. 1a).

There is evidence that compartments do influence the paths followed and the connections formed by sensory axons in the central nervous system. The particular route taken by an axon apparently depends not only on the type of receptor from which it originates, but also on the developmental compartment in which its cell body is located<sup>3</sup>. Furthermore, the reflex responses elicited by stimulation of similar receptors seem to depend on the compartment in which the sensory cell bodies lie<sup>4</sup>. Here we have investigated whether the organization of peripheral axonal pathways is also influenced by compartments.

All the known receptor cells in the wings of wild-type Drosophila are located in the anterior compartment (Fig. 1a)<sup>5,6</sup>. To examine the hypothesis that the A-P compartment boundary of the wing forms a barrier to axon growth, one needs receptors in the posterior compartment whose axons could potentially join the anterior nerve bundles. Flies carrying  $Hairy\ wing\ (Hw)$ , a dominant, sex-linked mutation, provide suitable material for study. This mutation causes both sensory bristles and campaniform sensilla (disk-shaped cuticular strain detectors) to form in many regions of the cuticle normally devoid of receptors, including the posterior compartment of the wing. Supernumerary receptors are found on veins L2, L3, L4, L5, the anterior cross vein and occasionally on the radial vein, as well as in the inter-vein areas (Fig. 1b).

The anterior cross vein (ACV) connects vein L4 (posterior) with vein L3 (anterior), and thus forms a potential conduit for axon growth between the two compartments. In wild-type flies this vein carries a single sensillum, located in the anterior compartment (Fig. 2a). Its cell body usually lies at or near the L3-ACV junction, and its dendrite travels through the ACV to attach to the dome of the sensillum. In Hw flies, one or more supernumerary sensilla may be present on the ACV, and extra sensilla may also occur on L4 near the ACV (Fig. 2b-d). In all such cases we have analysed, the axons pass through the ACV to join the nerve travelling through L3. If the cell body lies in L4 distal to the ACV (Fig. 2c), its axon makes a right angle turn to enter the ACV. If the cell body is located proximal to the ACV (Fig. 2d) its axon, in addition, first travels distally, the opposite of the usual direction. The preference of supernumerary axons in this region for following the ACV and L3 is not due to the inability of L4 to support axon growth. This is evident because the axons of distal receptors travel successfully in L4 before turning into the ACV, and receptors nearer to the proximal end of the vein commonly send their axons as a bundle through it towards the base of the wing.

Even though the nerve bundles formed by the more proximal receptors often travel towards the base of the wing, both single axons and large nerve bundles can also grow at right angles to the veins, cross the compartment boundary and join the major nerves in L3 or the radial vein (Fig. 3). The supernumerary receptors in these more proximal regions of the posterior compartment include many bristles as well as campaniform sensilla. Thus, the axons of both receptor classes readily cross the A-P boundary, and crossing is not confined to any particular location on the wing. The ACV provides an open channel, but well defined veins are not required for axons to cross into the anterior compartment.

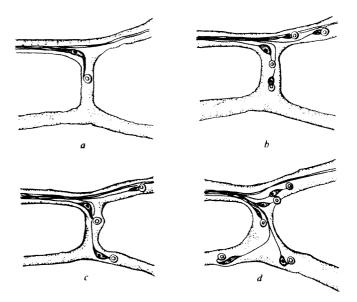

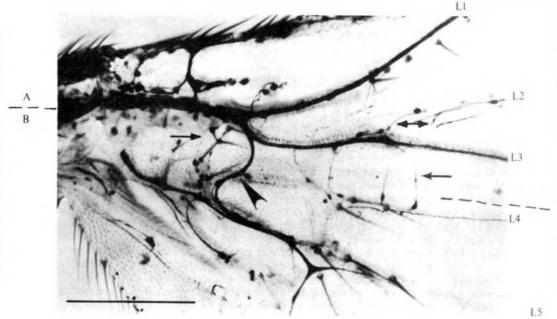

Fig. 2 Course of axons in the region of the anterior cross vein (ACV). a, Wild-type fly with one campaniform sensillum, its cell body at the ACV-L3 junction and its axon travelling through L3. Proximal is to the left in each drawing, distal to the right. b-d, Examples of homozygous Hw animals. Campaniform sensilla and their cell bodies are found in the posterior compartment, and their axons turn into the ACV, cross the compartment boundary and join the nerve bundle in L3. Hemizygous males and heterozygous females, which have fewer supernumerary receptors, show similar patterns. Drawn from preparations stained with methylene blue. Stain (Methylene Blue Ehrlich, Chroma,  $0.05 \text{ g ml}^{-1}$ ) was injected into the thorax of adult flies and the wings were removed after 0.5-4 h and mounted in a drop of mineral oil. Contrast could often be enhanced by using differential interference optics. Over 100 wild-type and mutant flies with adequate staining were analysed.

Fig. 3 Course of axons in the proximal wing of a homozygous Hw fly. A massive nerve bundle from the posterior compartment (◄) joins the normal anterior nerves at the confluence of veins L1 and L3. Numerous single axons cross from L4 to L3 (←), from scattered posterior receptors to the radial vein (→), and from L2 to L3 (↔). The location of the compartment boundary is indicated by the dashed lines in the margin (compare with Fig. 1). Methylene blue staining as in Fig. 2. Scale bar, 200 µm.

We have used Hairy wing flies to probe the potential barrier to axon growth at the A-P compartment boundary. However, it is conceivable that the Hw mutation, in addition to producing supernumerary receptors, might shift or eliminate the very A-P compartment boundary whose properties we want to analyse. If this were the case, sensilla which we believe to be in the posterior compartment on the basis of their location would actually be anterior in character and their axons would not be crossing a compartment boundary. To test this possibility, we induced large clones of cells marked with the mutation multiple wing hairs (mwh) in Hw flies (see Fig. 1 legend). These clones were confined to the same areas, and defined the compartment boundary in the same location, as in wild-type flies in all the genotypes we used for axon tracing: Hw/Hw females, Hw/+ females and Hw/Y males. Thus, there is no indication that Hwaffects the compartment boundary. Furthermore, if the existence of the boundary is the outcome of affinity differences between anterior and posterior cells, these differences must also be present in Hw flies and must be irrelevant to the growth of adult axons.

Our clones were marked with the mutation yellow (y) in addition to mwh, so that the sensory bristles could also be scored. We never found y bristles in wild-type tissue or wildtype  $(y^+)$  bristles in a y clone. These observations argue strongly against the possibility that anterior bristle precursor cells have migrated into the posterior compartment.

Thus, adult axons can freely cross the A-P compartment boundary. On their way to the central nervous system they also cross at least the proximo-distal boundary in the wing. On the other hand, Lawrence<sup>8</sup> reported that sensory axons do not cross segment borders in the abdomen of the milkweed bug Oncopeltus. Furthermore, he showed that clones in the epidermis are restricted early in development to an individual segment. Thus, the segment border is a compartment border on this criterion. However, the present demonstration that the A-P compartment boundary does not constitute a barrier to the growth of axons indicates that in this respect segment borders have properties which not all other compartment boundaries share.

The developmental history of axon growth in the wing is incompletely known, but the course of axons in the adult is presumably a consequence of a pattern laid down earlier. Waddington9 reported the presence of 'nerve bundles' in veins L1 and L3 of the metamorphosing wing before the differentiation of the adult sensory cells. Preliminary studies using the electron microscope 10 indicate that these structures are much

more complex than he realized, but the time of their appearance and their localization are reminiscent of the pioneer axons which have more recently been described in other insect appendages<sup>11-13</sup>. Experimental evidence for the causal role of such axons in the organization and placement of peripheral nerves is now available14. Whatever guiding factors are present in the wing, however, be they 'pupal nerves', pioneer axons, or specific non-neural substrates, we expect them to be localized primarily in veins L1 and L3. Not only are these the veins in which adult nerves are normally present, but axons from ectopic receptors often leave a particular vein at apparently arbitrary points to join the fibres travelling in L1 and L3. Figure 3 shows one example of the many we have seen of axons crossing from both L2 (an anterior vein) and L4 (a posterior vein) to join the nerve in L3.

We consider it a reasonable working hypothesis that the filopodia of growing adult axons explore the nearby territory and if a suitable guiding factor is available they follow it preferentially and with the correct polarity. If the normal guiding factor is not available, other features of the environment may influence the growth of the axon but correct polarity may not be achieved (unpublished observations). In this process, compartments and the boundaries between them appear not to be important.

We thank Peter Lawrence for suggestions and for comments on an early draft of the manuscript. This work was supported by NIH grant NS-07778 and NSF grant BNS-7914111.

# Evidence for expression of the paternal genome in the two-cell mouse embryo

Janet A. Sawicki, Terry Magnuson & Charles J. Epstein

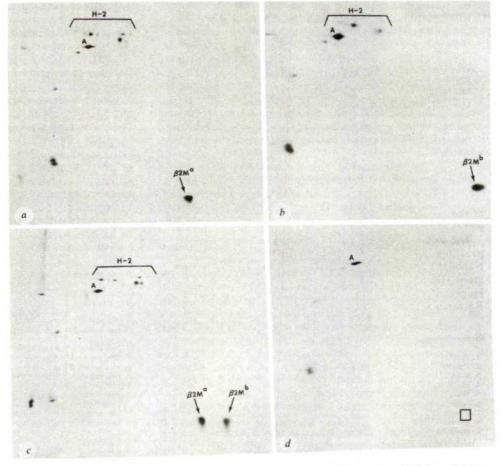

Departments of Pediatrics and of Biochemistry and Biophysics, University of California, San Francisco, San Francisco, California 94143, USA

Although there is strong evidence that the paternal genome is activated at the four- to eight-cell stage of mouse embryogenesis1-12, studies to date have been restricted because of their dependence on the manifestations of gene products, such as enzyme activity and cell-surface expression, rather than on direct assay of their synthesis.  $\beta_2$ -microglobulin ( $\beta_2$ M), a 12,000-molecular weight  $(M_r)$  peptide associated with several of the gene products encoded by the H-2-Tla complex in the mouse  $^{13-17}$ , is synthesized by early cleavage stage embryos (J.A.S., T.M. and C.J.E., unpublished). The existence of an electrophoretic variant of \( \beta\_2 M \) in inbred strains has recently been described18-20, and tryptic peptide mapping19 and amino acid sequencing data21 indicate that the primary sequences of these variants differ by a single amino acid, thus establishing the genetic basis for this variation. Mice heterozygous at the  $\beta_2$ m locus synthesize both forms,  $\beta_2 M^a$  and  $\beta_2 M^b$  (refs 18, 20). Using direct immunoprecipitation and two-dimensional gel electrophoresis, we have used this variation at the  $\beta_2$ m locus to distinguish between maternal and paternal \( \beta\_2 M \) and have now established that the synthesis of paternally derived  $\beta_2 M$  is first detectable at the two-cell stage. This is the earliest stage at which expression of the mammalian embryonic genome has been established22.

Autoradiograms Fig. immunoprecipitated polypeptides from <sup>35</sup>S-methionine-labelled lymphocytes from the splenic parental inbred strains. a, SWR/J lymphocytes, anti- $\beta_2 M$ ; C57BL/6, anti-\(\beta\_2\text{M}\); c, SWR/J anti-BaM+ lymphocytes, C57BL/6 lymphocytes, anti-β<sub>2</sub>M; d, SWR/J lymphocytes, preimmune serum. Radiolabelling of lymphocytes and preparation of gels were done as previously described<sup>23</sup>. Briefly, lymphocytes were isolated and labelled for 6 h (3×10<sup>7</sup> cells per ml per 250μCi 35S-methionine) in Dulbecco's modified Eagle's medium lacking methionine. Aliquots of cell extracts prepared in 0.5% NP40 were reacted with antiserum for 15 min at 4 °C after which a suspension of S. aureus protein A (10% wt/vol) (Enzyme Center) was added and the mixture was incubated for an additional 10 min at 4°C. Protein A-bound immune complexes were released by the addition of O'Farrell's lysis buffer<sup>24</sup>. The immunoprecipitates were analysed on two-dimensional gels. Non-equilibrium pH gradient gels having an approximate pH range of 4.5-7.9 were used as the first dimension<sup>25</sup>. Electrophoresis was carried out for 4 h at 400 V. Separation in the second dimension was done using a 4.5% polySWR/J superovulated female mice carrying the  $\beta_2 m^a$  allele were mated to C57BL/6 males carrying the  $\beta_2 m^b$  allele, and standard procedures were used to obtain fertilized eggs and preimplantation mouse embryos. Embryos from the reciprocal mating (C57BL/69×SWR/Jd) were also collected. The embryos were radiolabelled with <sup>35</sup>S-methionine, protein extracts were prepared and reacted with a rabbit anti-mouse  $\beta_2$ M serum and the antigen-antibody complexes were precipitated with protein A derived from Staphylococcus aureus, Cowan I strain. After release of the complexes from the immunoabsorbent, the immunoprecipitates were analysed by two-dimensional polyacrylamide gel electrophoresis and autoradiography.

Three criteria are used to verify the identity of the  $\beta_2 M^a$  and  $\beta_2 M^b$  peptides on the two-dimensional gels: (1) The peptides are not precipitated by preimmune rabbit serum. (2) Each peptide has a  $M_r$  of 12,000 and an isoelectric point of 6.7. The apparent  $M_r$  of  $\beta_2 M^a$  is slightly higher than that of  $\beta_2 M^b$ , while the apparent isoelectric point of  $\beta_2 M^b$  is slightly higher than that of  $\beta_2 M^a$  (Fig. 1). (3) Each peptide co-migrates with a purified preparation of either  $\beta_2 M^a$  or  $\beta_2 M^b$ .

Using this procedure, we tested fertilized eggs and two-, four- and eight-cell embryos heterozygous at the  $\beta_2 m$  locus and determined that the synthesis of paternally derived  $\beta_2 M$  is detectable as early as the two-cell stage (Fig. 2c). However, although  $\beta_2 M$  synthesis is readily detectable in unfertilized eggs (unpublished), we were unable to detect the synthesis of either maternally or paternally derived  $\beta_2 M$  in fertilized eggs (Fig. 2a, b). This finding, coupled with the observation that maternally and paternally derived  $\beta_2 M$  are apparently synthesized in approximately equal amounts in two-, four- and eight-cell embryos (Fig. 2c, d), suggests that maternally derived  $\beta_2 M$  messenger RNA is either degraded or otherwise inactivated at the time of fertilization and that the observed synthesis of  $\beta_2 M$ 

acrylamide stacking gel and a 14% polyacrylamide separation gel. The square in d indicates the site to which  $\beta_2 M$  would migrate on the gel. 'A' indicates actin, which has a  $M_\tau$  of 44,000. The basic side of each gel is on the right.

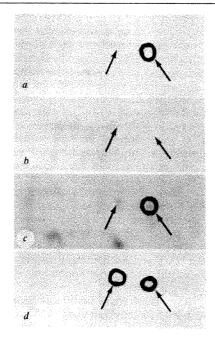

Fig. 2 35S-methionine-labelled peptides immunoprecipitated with rabbit anti-mouse  $\beta_2 M$  serum from: a, fertilized eggs, SWR/J $\circ$  C57BL/6 $\circ$ ; b, fertilized eggs, C57BL/6 $\circ$  SWR/J $\circ$ ; c, two-cell embryos, C57BL/6 $\circ$  SWR/J $\circ$ ; d, four-cell embryos, C57BL/6 $^{\circ}$  ×SWR/J $^{\circ}$ . The panels represent comparable regions from four two-dimensional gel autoradiograms. For each gel, 200-400 fertilized mouse eggs or preimplantation mouse embryos were obtained from superovulated females. Embryos were transferred to 30 µl of modified Whitten's medium<sup>26,27</sup> containing <sup>35</sup>S-methionine (specific activity 800-1,200 Ci mmol<sup>-1</sup>) (Amersham/Searle) at a concentration of 2 mCi/ml<sup>-1</sup> and cultured under paraffin oil at 37 °C in a 5% CO<sub>2</sub> atmosphere for 4 h. At the end of the incubation period, embryos were solubilized in 100 µl of 0.5% NP40 (Particle Data Inc.) in Tris-buffered saline (150 mM NaCl, 50 mM Tris, 0.02% NaN<sub>3</sub>, pH 7.0). Each extract was centrifuged at 10,000g for 5 min in a Beckman microfuge B to remove unlysed nuclei, and the supernatants were stored at -80 °C. Immunoprecipitates were prepared as described in Fig. 1 legend. In a and c, purified mouse  $\beta_2 M^b$  (2.75 µg) was added to each immunoprecipitate sample before electrophoresis, while in d, both purified  $\beta_2 M^a$  $(2.75 \mu g)$  and  $\beta_2 M^b$   $(2.75 \mu g)$  were added. Proteins were fixed and stained with 50% trichloroacetic acid-0.1% Coomassie blue, the gel was dried, and the stained  $\beta_2 M$  spot(s) was circled with radioactive ink. The arrows in a and b indicate the absence of  $\beta_2 M^a$ and  $\beta_2 M^0$ , while the arrows in c and d indicate their presence. Each gel was exposed to X-ray film for  $\sim 2 \times 10^6$  count-days (c.p.m. loaded on to gel × no. of days exposed).

at the two-cell stage is in fact the result of activation of the embryonic genome.

The rabbit anti-mouse  $\beta_2 M$  serum and purified  $\beta_2 M$  preparations were provided by Dr Ettore Appella from the National Cancer Institute. This work was supported by NIH grant HD-03132. C.J.E. was an investigator of the Howard Hughes Medical Institute. T.M. is a recipient of a NIH National Research Service Award.

## Regulation of epithelial tight junction permeability by cyclic AMP

Michael E. Duffey, B. Hainau, Shu Ho & Carl J. Bentzel\*

Departments of Physiology and Medicine, State University of New York at Buffalo and Buffalo Veterans Administration Medical Center, Buffalo, New York 14215, USA

In 'leaky' epithelia, ions move through both a transcellular and a paracellular (serial alignment of tight junction and intercellular space) path. The efficiency of transepithelial transport could therefore be regulated if the cell was able to alter reversibly the permeability of tight junctions. (These are specialized regions of the apical cell membranes common to all epithelia.) We now report that such a mechanism indeed exists in the Necturus gallbladder. It is effected by cyclic AMP, which is already known to mediate surface membrane phenomena in a variety of cell systems through its interaction with the cytoskeletal system<sup>1,2</sup>, In gallbladders mounted and perfused with electrolyte solutions in an Ussing-type chamber, exposure of the mucosal surface to cyclic AMP analogues increased transepithelial electrical resistance, potential difference and short-circuit current and decreased NaCl dilution potentials in a rapid and reversible manner. We also observed rapid depolarization of cell membrane electrical potentials and a slow decline in intracellular K+ activity. Freeze-fracture electron microscopy of tissues fixed with glutaraldehyde during the peak electrical response showed a reorientation of intramembranous junctional fibrils, suggesting that cyclic AMP reduces the ionic permeability of the paracellular pathway in this epithelium by altering the structure of tight junctions.

After decapitating the animals, gallbladders were removed, washed and mounted mucosal side up between two halves of a Plexiglass chamber. The tissue was loosely stretched over a 0.13-cm<sup>2</sup> chamber opening and sealed with vacuum grease between chamber halves. Tissues were bathed on both sides by a continuous flow of amphibian Ringer's solution. Transepithelial resistance  $(R_t)$ , spontaneous electrical potential difference  $(\psi_{ms})$ and short-circuit current (Isc) were measured with the fourelectrode technique described in Fig. 1 legend. Mucosal cell membrane electrical potentials ( $\psi_{mc}$ ) were measured with a high-impedance electrometer by advancing a microelectrode  $(1 \text{ M KCl}, > 10 \text{ M}\Omega)$  tip resistance) into the cells from the mucosal bath. NaCl dilution potentials were measured as the change in steady-state  $\psi_{ms}$  observed when one-half of the NaCl in the mucosal bath was replaced isosmotically with sucrose. No correction was made for liquid junction potentials because control, experimental and recovery measurements were made with the same solutions for the same gallbladder.

The gallbladders were also studied morphologically. They were fixed in situ by simultaneously applying a phosphatebuffered 2% glutaraldehyde solution to the mucosal and serosal surfaces. Freeze-fracture was performed at -100 °C in pre-

<sup>\*</sup> To whom reprint requests should be addressed.

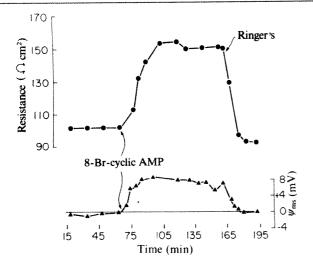

Fig. 1 Time course of a typical experiment showing a reversible increase in transepithelial electrical potential difference ( $\psi_{ms}$ ,  $\triangle$ ) and resistance ( $\bigcirc$ ) on addition of  $10^{-3}$  M 8-Br-cyclic AMP to mucosal bath of gallbladder mounted in an Ussing-type chamber. Composition of bathing solution (mM): NaCl, 87; KCl, 4.5; CaCl<sub>2</sub>, 1.8; MgCl<sub>2</sub>, 1.0; KH<sub>2</sub>PO<sub>4</sub> 0.7; NaHCO<sub>3</sub>, 7.5; HEPES buffer, 5.0; pH 7.4, when equilibrated with 99% O<sub>2</sub>, 1% CO<sub>2</sub> at 25 °C. Transepithelial electrical potential difference ( $\psi_{ms}$ , measured with respect to the mucosal bath, bottom trace), transepithelial resistance ( $R_t$ , top trace) and short-circuit current ( $I_{sc}$ , not shown in figure) were measured by an automatic voltage-clamp electrometer in which solution resistance was automatically subtracted.  $\psi_{ms}$  was measured by calomal electrodes using 1 M NaCl or 3 M KCl-filled agar bridges;  $R_t$  was measured by passing 100- $\mu$ s bipolar current pulses (75  $\mu$ A cm<sup>-2</sup>) through the tissue via Ag/AgCl electrodes; and  $I_{sc}$  was measured by passing a current sufficient to reduce  $\psi_{ms}$  to zero.

viously fixed tissue impregnated with 20% glycerol (Denton DFE-3 apparatus) and examined with a Siemens 1A electron microscope.

Control electrophysiological parameters are summarized in Table 1 and are in general agreement with those measured by other investigators<sup>3-5</sup> who have also noted a low  $R_t$  in this epithelium. Figure 1 shows a typical experiment. After the baseline  $\psi_{\rm ms}$  and  $R_t$  stabilized, the mucosal bathing solution was replaced by an identical Ringer's solution containing  $10^{-3}$  M 8-bromo-cyclic AMP (8-Br-cyclic AMP).  $R_t$  and  $\psi_{\rm ms}$  began to increase within 5-10 min and peaked by 30-75 min. Reversibility was indicated by a return of electrical parameters to baseline when the 8-Br-cyclic AMP mucosal bathing solution was replaced by the standard Ringer's solution. Note that, within 5-10 min, 8-Br-cyclic AMP depolarized  $\psi_{\rm mc}$  and  $\psi_{\rm cs}$  (the basolateral membrane potential), while  $R_{\rm m}/R_{\rm s}$  decreased and  $I_{\rm sc}$  increased (Table 1). The decline in K<sup>+</sup> activity  $(a_{\rm K}^+)$  was

gradual during exposure to 8-Br-cyclic AMP. When the mucosal bathing solution was again replaced with the control electrolyte solution (recovery), all parameters, except  $a_{\rm K}$ , which rose to a value above the control value, returned within 15 min to near control values. In four separate tissues, mucosa positive dilution potentials (with respect to serosa) were reduced from  $15.3 \pm 0.4 \, {\rm mV}$  (control) to  $12.0 \pm 0.9 \, {\rm mV}$  (8-Br-cyclic AMP) and returned to  $13.9 \pm 0.8 \, {\rm mV}$  (recovery), P < 0.01.

In dose-response experiments, we determined the fractional peak change in transepithelial resistance  $(\Delta R_t)$  to various mucosal concentrations of 8-Br-cyclic AMP.  $\Delta R_t$  increased linearly with increasing mucosal concentrations. At 10<sup>-5</sup> M (n=3) there was no change in  $R_t$  and at  $10^{-2}$  M (n=3)  $R_t$ increased to 1.5 times the control value. A comparable  $\Delta R_t$  was observed when 8-Br-cyclic AMP was dissolved in the serosal bath, except that response and recovery were delayed. On a molar basis, the cyclic AMP analogue 8-p-chlorophenylthiocyclic AMP produced a greater response than 8-Br-cyclic AMP; dibutyryl cyclic AMP produced a lower response. 10<sup>-3</sup> M isobutyl-1-methylxanthine, a phosphodiesterase produced a 12% increment in R. However, a 25% increment was observed when the mucosal tissue surface was pretreated with 10<sup>-5</sup> M 8-p-chlorophenylthio-cyclic AMP, a concentration which by itself did not increase resistance. 8-p-chlorophenylthio-cyclic GMP  $(10^{-5}-10^{-4} \text{ M})$  reduced  $R_t$ , but the dose-response relationship was not linear and  $\psi_{\rm ms}$  did not change.

In thin-section electron micrographs, gallbladders treated with  $10^{-3}$  M 8-Br-cyclic AMP demonstrated thickening and aggregation of microfilaments in submembranous regions, particularly those adjacent to tight junctions. Epithelia fixed with glutaraldehyde within 5 min of exposure to 8-Br-cyclic AMP ( $10^{-3}$  M) and freeze-fractured showed basal strands in focal regions extending well below the main fibrillar meshwork. By 30 min (peak effect) this finding was more pronounced with occasional isolated strands appearing below the meshwork, resulting in an increase in number of strands and a longitudinal lengthening of the junction (Fig. 2). These morphological changes are expressed semiquantitatively by morphometric analysis (Table 2). Intercellular space morphology did not show appreciable change.

If an external current is applied across *Necturus* gallbladder, >90% of the current flows paracellularly<sup>3,6</sup> through the tight junction and intercellular space in series. Therefore,  $R_t$  is dominated by the ionic conductance of the paracellular pathway. Na<sup>+</sup> absorption in this tissue is characterized by an electroneutral NaCl-coupled mucosal influx<sup>4</sup> and the leaky paracellular shunt, both of which are responsible for the observed near-zero  $I_{sc}$  and  $\psi_{ms}$  during control conditions. The increase in  $R_t$ ,  $I_{sc}$  and  $\psi_{ms}$  observed in 8-Br-cyclic AMP-treated tissues is consistent with reduced paracellular shunting, probably due to a reduced ionic permeability of the tight junction. A chemical or physicochemical alteration of fixed charge within the transjunctional path might decrease Na<sup>+</sup> or increase Cl<sup>-</sup> conductance, causing the observed reduction in dilution potentials. On
